INFORMATION SECURITY AND MANAGEMENT LAB

CONSOLIDATED LAB EXPERIMENTS

EXPERIMENT 1

Aim:

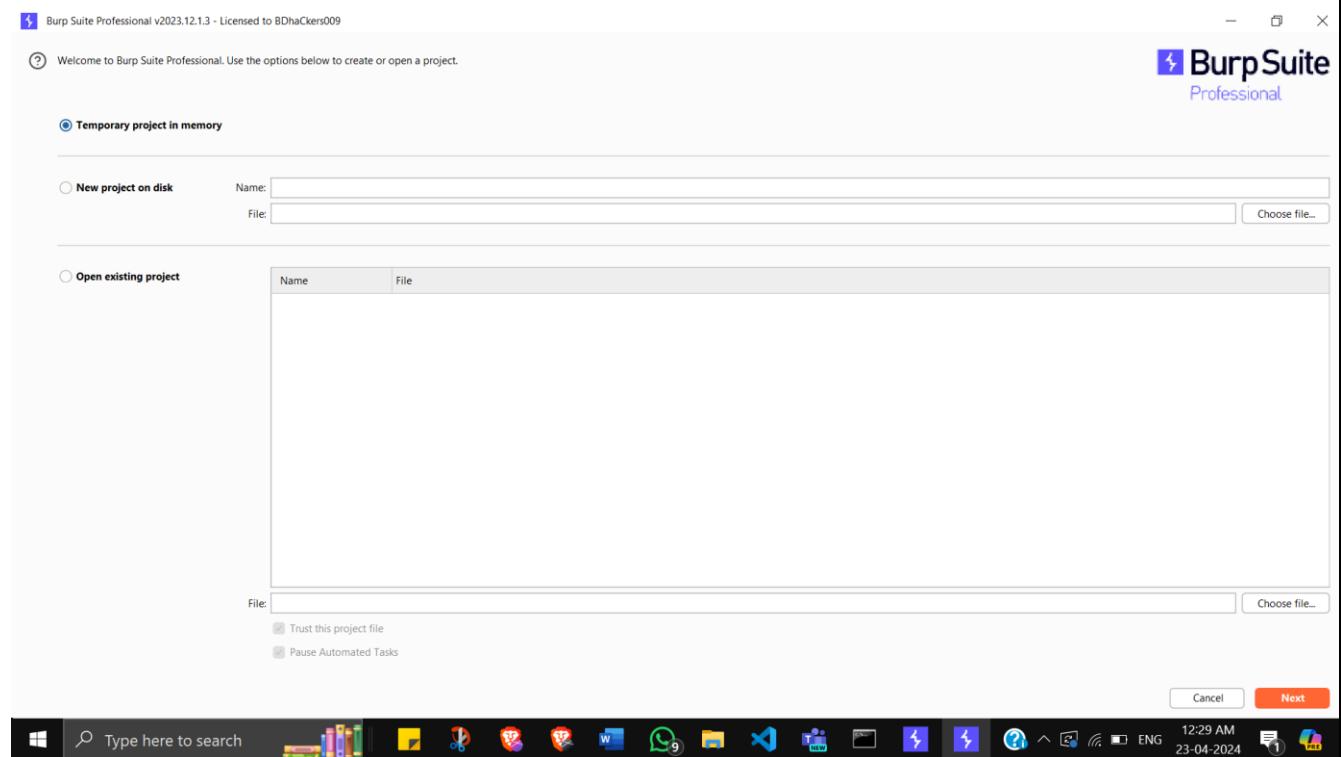

To study about the tool Burp Suite and Intercept the connection between the system and the internet.

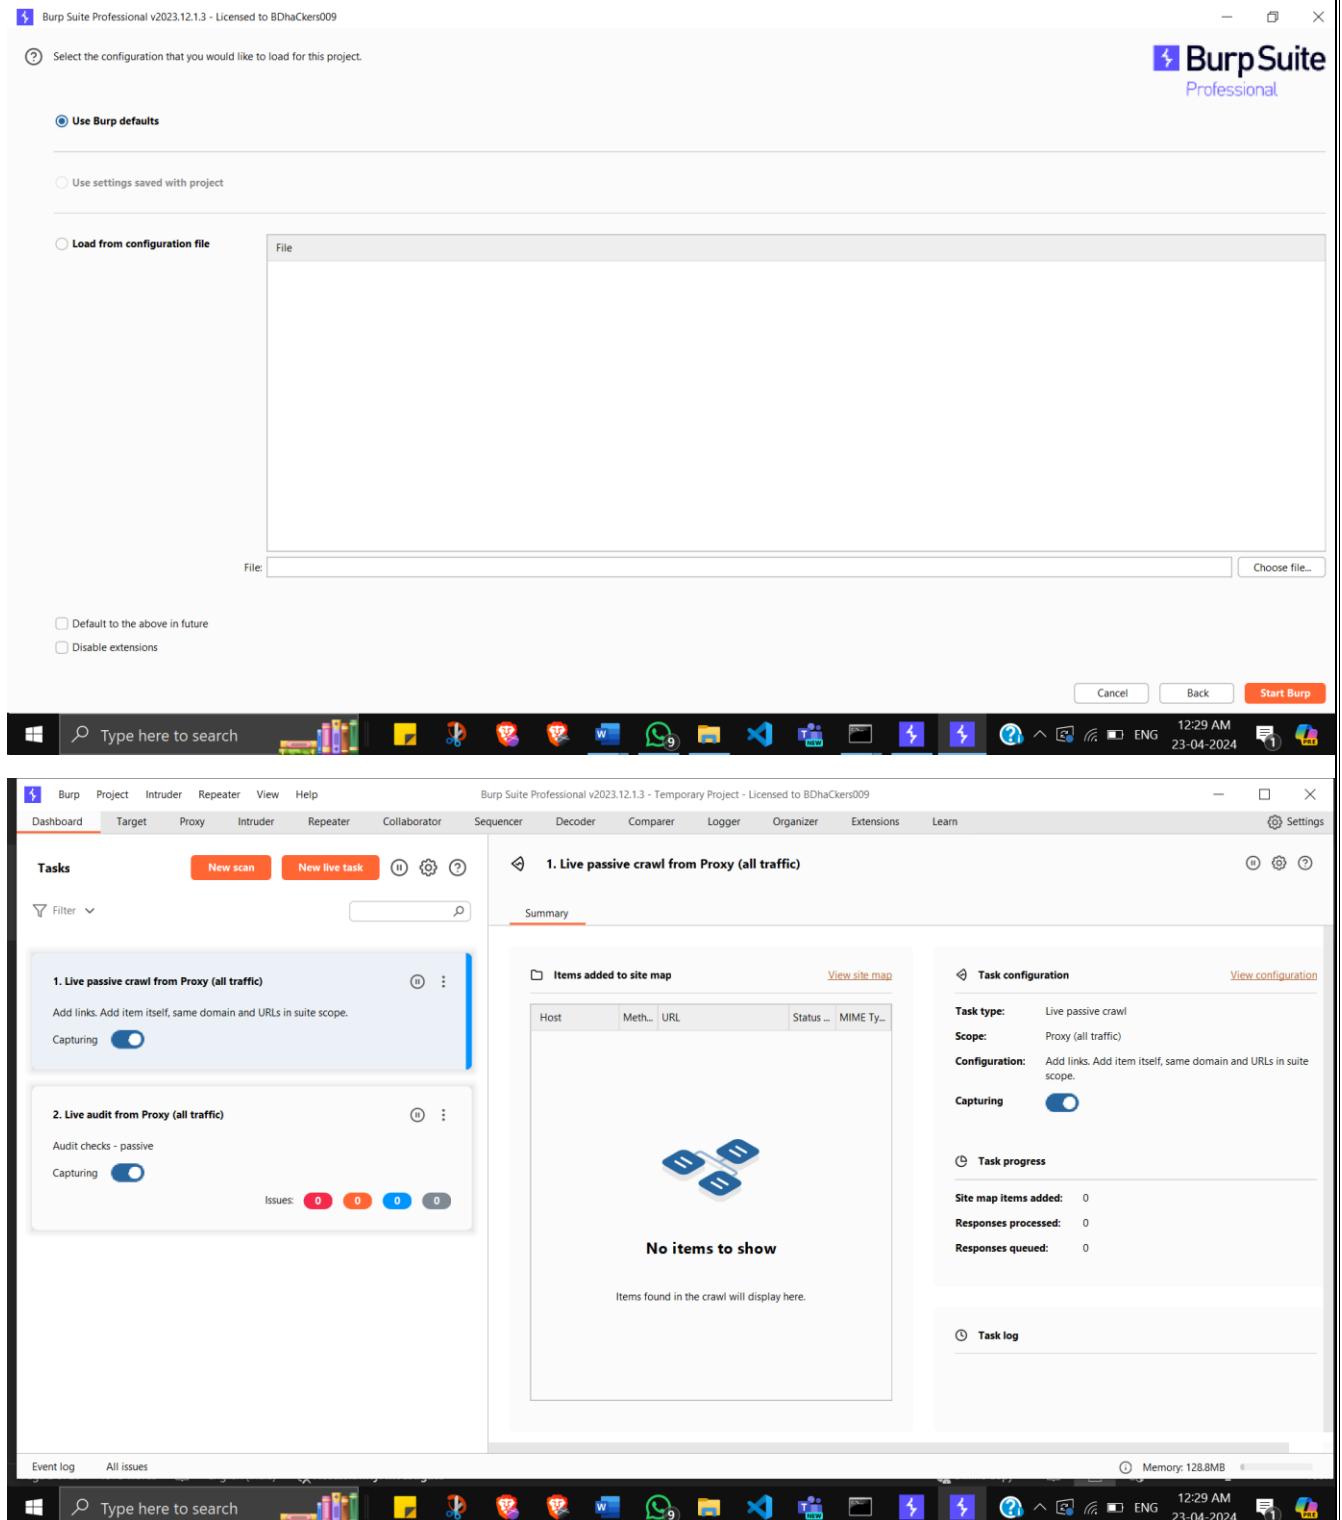

Apparatus Required:

Burp Suite

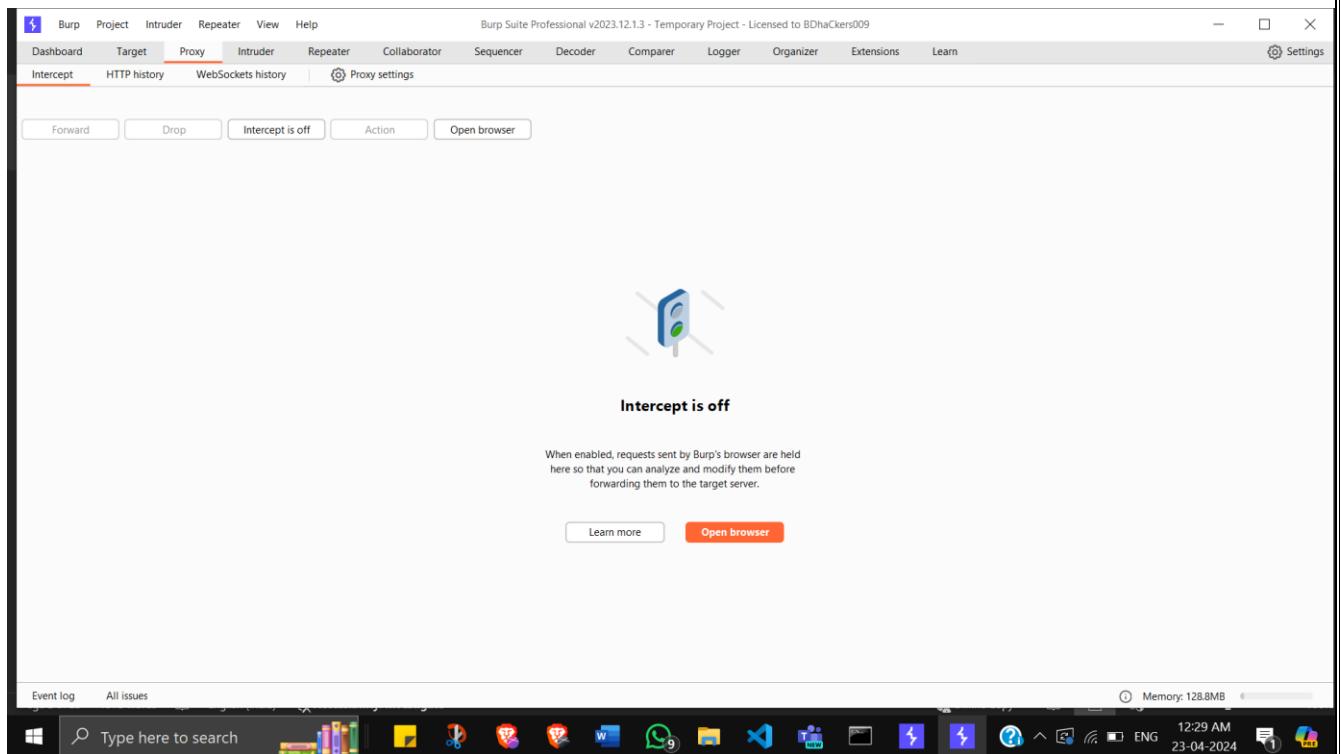

Procedure:

Step 1: Download Burp Suite and open it.

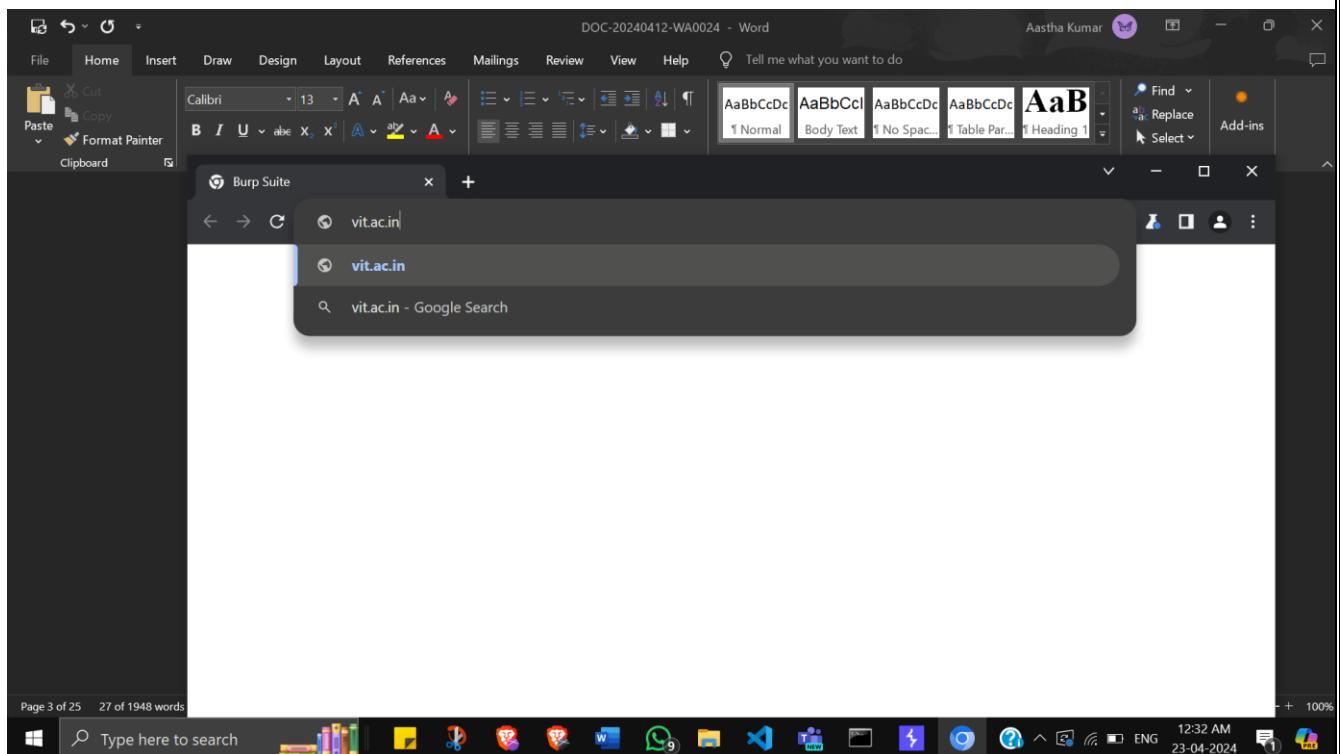

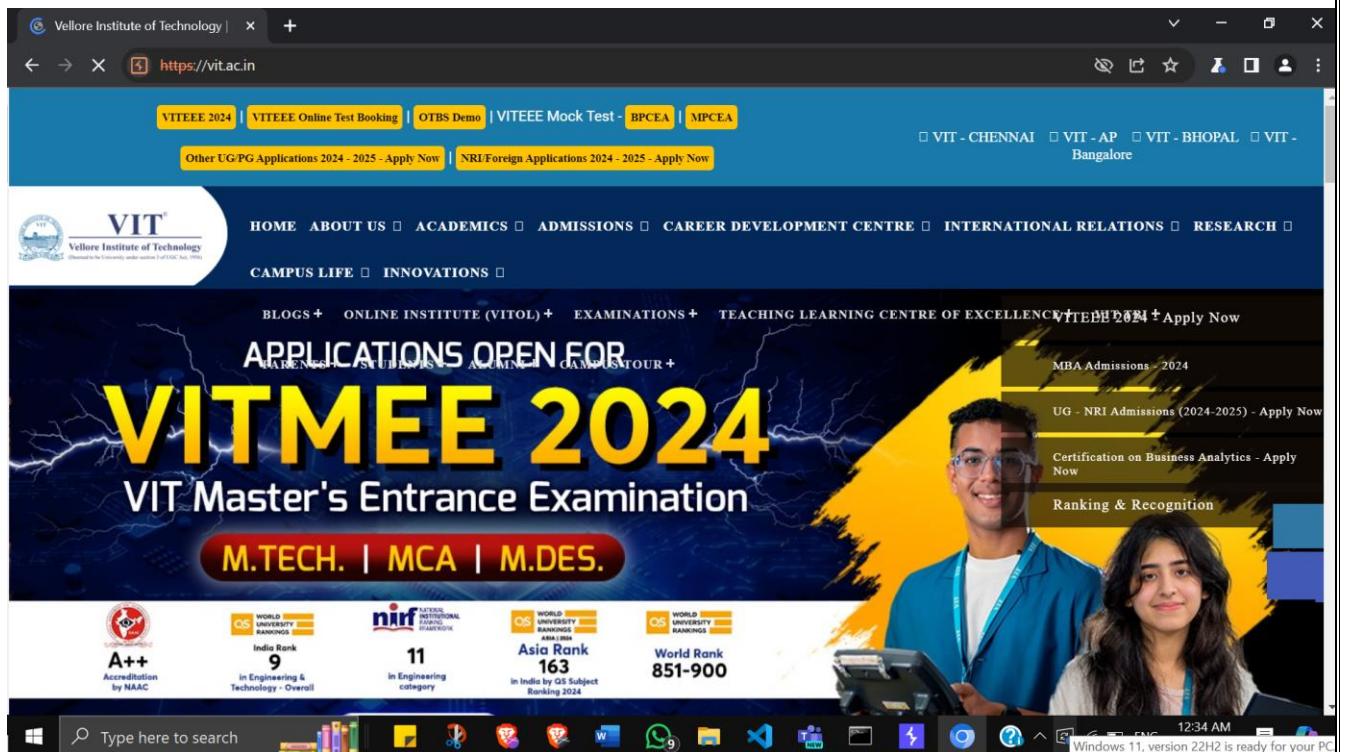

Step 2: Go to Proxy tab and click “Open Browser”

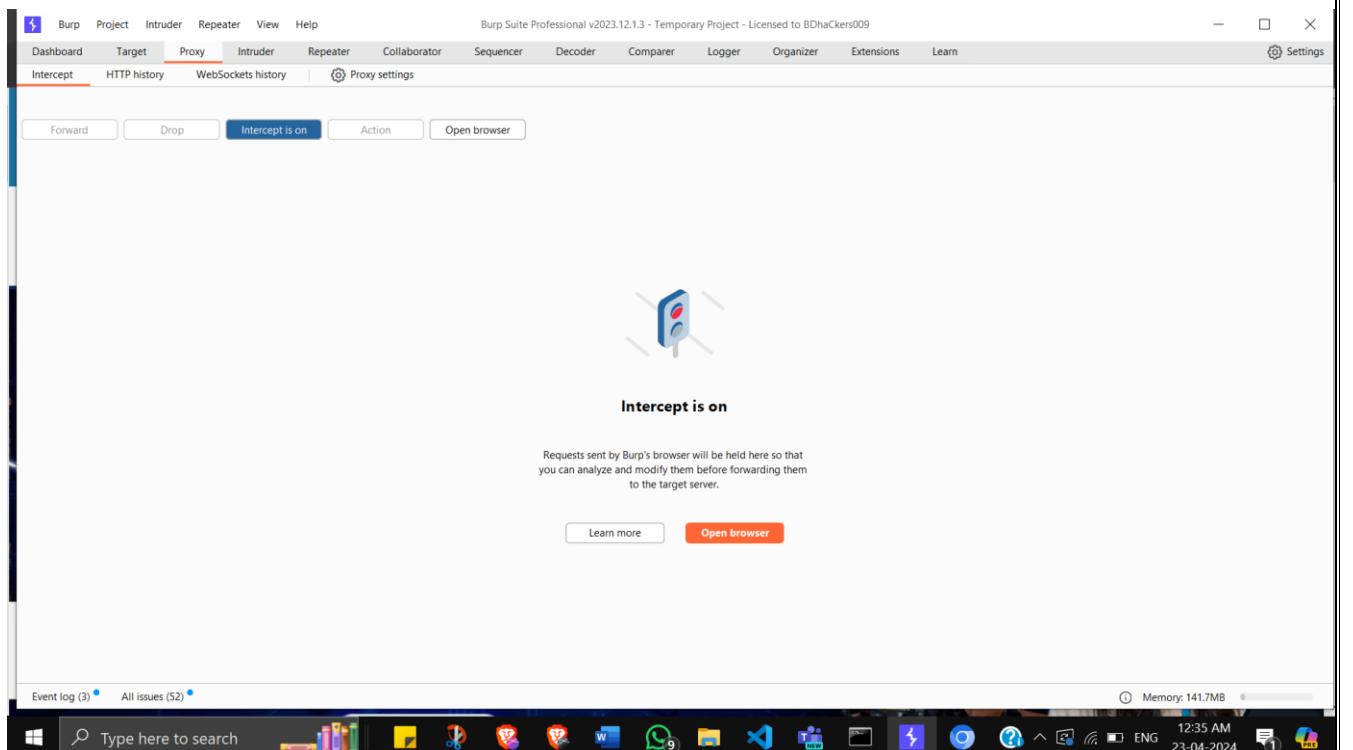

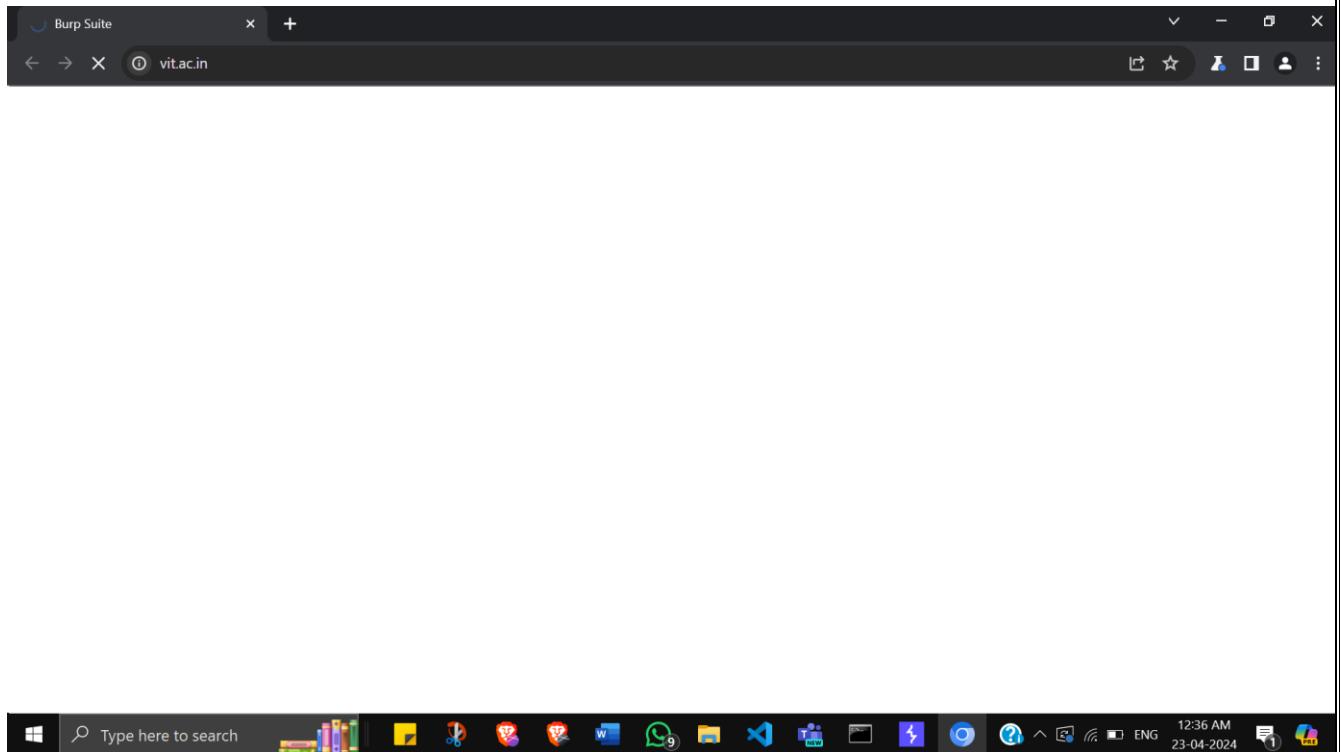

Step 3: Type in vit.ac.in in the search bar and wait for results. You will notice that the site loads without any timeout error because the intercept is off.

Step 4: Now go back to Proxy tab and switch on the intercept. Try loading the same site again. This time you will face timeout error.

It will send a request but will then be stuck waiting for a response

Step 5: In BurpSuite, we can view the request sent

The screenshot shows the Burp Suite interface with the following details:

- Project:** vit.ac.in
- Tab:** Proxy (highlighted in red)
- Request:** GET / HTTP/1.1
- Headers:**
 - Host: vit.ac.in
 - Cookie: has_js=1; _ga_VY3TWN1fJ7=g01.1.1713812656.1.0.1713812656.60.0.0; _ga=GAI.1.1458883120.1713812656
 - Cache-Control: max-age=0
 - Sec-Ch-Ua: "Chromium";v="121", "Not A(Brand";v="99"
 - Sec-Ch-Ua-Mobile: ?0
 - Sec-Ch-Ua-Platform: "Windows"
 - Upgrade-Insecure-Requests: 1
 - User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/121.0.6167.85 Safari/537.36
 - Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/avif,image/webp,image/apng,*/*;q=0.8,application/signed-exchange;v=b3;q=0.7
 - Sec-Fetch-Site: none
 - Sec-Fetch-Mode: navigate
 - Sec-Fetch-Dest: document
 - Sec-Fetch-User: ?0
 - Accept-Language: en-US,en;q=0.9
 - Priority: uFO,i
 - Connection: close
- Inspector Panel:** Shows Request attributes (2), Request query parameters (0), Request body parameters (0), Request cookies (3), and Request headers (17).
- Bottom Taskbar:** Shows the date/time as 23-04-2024 12:36 AM and the system memory usage as 1443MB.

If we click forward, the request will be sent to the server. The webpage will be visible again.

If we drop the request in Burp Suite, you will face timeout error.

Conclusion: Tools offered by BurpSuite

1. Proxy: BurpSuite contains an intercepting proxy that lets the user see and modify the contents of requests and responses while they are in transit.
2. Intruder: It is a fuzzer. This is used to run a set of values through an input point. The values are run and the output is observed for success/failure and content length.
3. Repeater: Repeater lets a user send requests repeatedly with manual modifications.
4. Sequencer: The sequencer is an entropy checker that checks for the randomness of tokens generated by the webserver. These tokens are generally used for authentication in sensitive operations: cookies and anti-CSRF tokens are examples of such tokens.
5. Decoder: Decoder lists the common encoding methods like URL, HTML, Base64, Hex, etc. This tool comes handy when looking for chunks of data in values of parameters or headers. It is also used for payload construction for various vulnerability classes. It is used to uncover primary cases of IDOR and session hijacking.
6. Extender: BurpSuite supports external components to be integrated into the tools suite to enhance its capabilities.
7. Scanner: The scanner is not available in the community edition. It scans the website automatically for many common vulnerabilities and lists them with information on confidence over each finding and their complexity of exploitation. It is updated regularly to include new and less known vulnerabilities.

EXPERIMENT 2

Aim:

Using Burp to Brute Force a Login Page

Experiment Objective:

The objective of this experiment is to demonstrate how to use Burp Suite to perform a brute force attack on a login page. By simulating an attack on the authentication mechanism of a web application.

Introduction:

Authentication is a critical aspect of application security, and a vulnerable authentication system can lead to unauthorized access to sensitive data and functionalities. This experiment aims to highlight the significance of secure authentication practices and the potential consequences of authentication bypass vulnerabilities.

Setup:

Software and Tools:

1. Burp Suite
2. Web browser
3. Access to a vulnerable web application

Experiment Steps:

1. Disable interception in the Burp Proxy tab and navigate to the login page of the target web application in your browser.
2. Enter credentials into the login form and submit the request.
3. View the captured request in the Burp Proxy "HTTP history" tab and right-click to send it to the Intruder.
4. Set the attack type to "Cluster bomb/ Sniper/ Battering ram/ Pitchfork" and configure the payload sets in the "Payloads" tab.
5. In the Intruder "Positions" tab, designate the "username" and "password" parameters as payload positions for Pitchfork/ Cluster bomb otherwise either of password or username for Sniper/ Battering ram attack.
6. Start the attack and observe the results in the Intruder attack window.
7. Analyze the responses to identify successful login attempts.
8. Use the gathered credentials to authenticate on the web application's login page to confirm the success of the brute force attack.

Attacks:

1. Sniper:

Attack type: **Sniper**

Payload positions

Configure the positions where payloads will be inserted, they can be added into the target as well as the base request.

Target: `http://localhost:5000` Update Host header to match target

Add Clear Auto Refresh

```

22 username=$shirt$ipassword=$pants$;

```

PAWNED nazarmi

Payload set	1	2
Payload type	Simple list	Simple list
Payload options	admin user1 user@123	pass password1 pass@123

Result:

Results	Positions	Payloads	Resource pool	Settings
Filter: Showing all items				
Requ...	Payload 1	Payload 2	Status code	Error
1	admin		200	<input type="checkbox"/>
2	user@123		200	<input type="checkbox"/>
3	user1		200	<input type="checkbox"/>
4	admin	pass	200	<input type="checkbox"/>
5	user@123	pass	200	<input type="checkbox"/>
6	user1	pass	200	<input type="checkbox"/>
7	admin	password1	200	<input type="checkbox"/>
8	user@123	password1	200	<input type="checkbox"/>
9	user1	password1	200	<input type="checkbox"/>
10	admin	pass@123	200	<input type="checkbox"/>
11	user@123	pass@123	200	<input type="checkbox"/>
12	user1	pass@123	200	<input type="checkbox"/>

Since, the 9th entry is different with a result length of 464, we can deduce it is the correct username password combination.

Observations and Results:

Therefore, we've established that employing a Cluster Bomb attack and exploring varied combinations within list1 and list2 enables us to proficiently utilize Burp Suite for implementing the brute force technique, ultimately allowing us to decipher our website's password successfully.

EXPERIMENT 3

Aim:

SQL injection vulnerability in WHERE clause allowing retrieval of hidden data

Experiment Objective:

The objective of this experiment is to demonstrate how to exploit a SQL injection vulnerability to bypass authentication on a vulnerable login page. By simulating a SQL injection attack, participants will understand the risks associated with improper input validation and the importance of secure coding practices in preventing such vulnerabilities.

Introduction:

SQL injection is a common vulnerability that occurs when an application fails to properly sanitize user-supplied input before using it in an SQL query. Attackers can exploit this vulnerability to manipulate the SQL queries executed by the application, potentially leading to unauthorized access, data leakage, and other security breaches. This experiment aims to illustrate the impact of SQL injection vulnerabilities on authentication mechanisms and the overall security of web applications.

Setup:

Software and Tools:

1. Burp Suite
2. Web browser
3. Access to a vulnerable web application

Instructions:

1. Install and configure Burp Suite on your system.
2. Download and set up a vulnerable web application.
3. Ensure that Burp Suite is correctly configured with your web browser for proxying HTTP requests.
4. Access the vulnerable login page of the web application in your browser.

Experiment Steps:

1. Disable interception in the Burp Proxy tab and navigate to the login page of the target web application in your browser.
2. Submit the login request with credentials and observe any error messages.
3. Modify the password parameter in the login page to inject a SQL code (e.g. admin ' or 1=1 --).
4. Verify if the SQL injection attack was successful by bypassing authentication.

Observations:

The SQL injection attack successfully bypassed the authentication mechanism, allowing access to the application as the administrator user.

' OR 1=1--

Results:

1. The experiment underscores the critical importance of implementing robust input validation mechanisms to mitigate the risk of SQL injection attacks.
2. Developers should utilize secure coding practices, such as parameterized queries and input sanitization, to prevent SQL injection vulnerabilities in their applications.
3. Security professionals should regularly assess and test web applications for SQL injection vulnerabilities.

EXPERIMENT 4

Aim:

Cross site scripting

Experiment Objective:

To understand and demonstrate the impact of Cross-Site Scripting (XSS) vulnerabilities in web applications using Burp Suite.

Introduction :

XSS vulnerabilities pose a significant threat by allowing attackers to inject malicious scripts into websites, leading to potential data theft, session hijacking, and other harmful consequences. This experiment provides an opportunity to delve into the realm of web security, emphasizing the importance of identifying and mitigating XSS vulnerabilities.

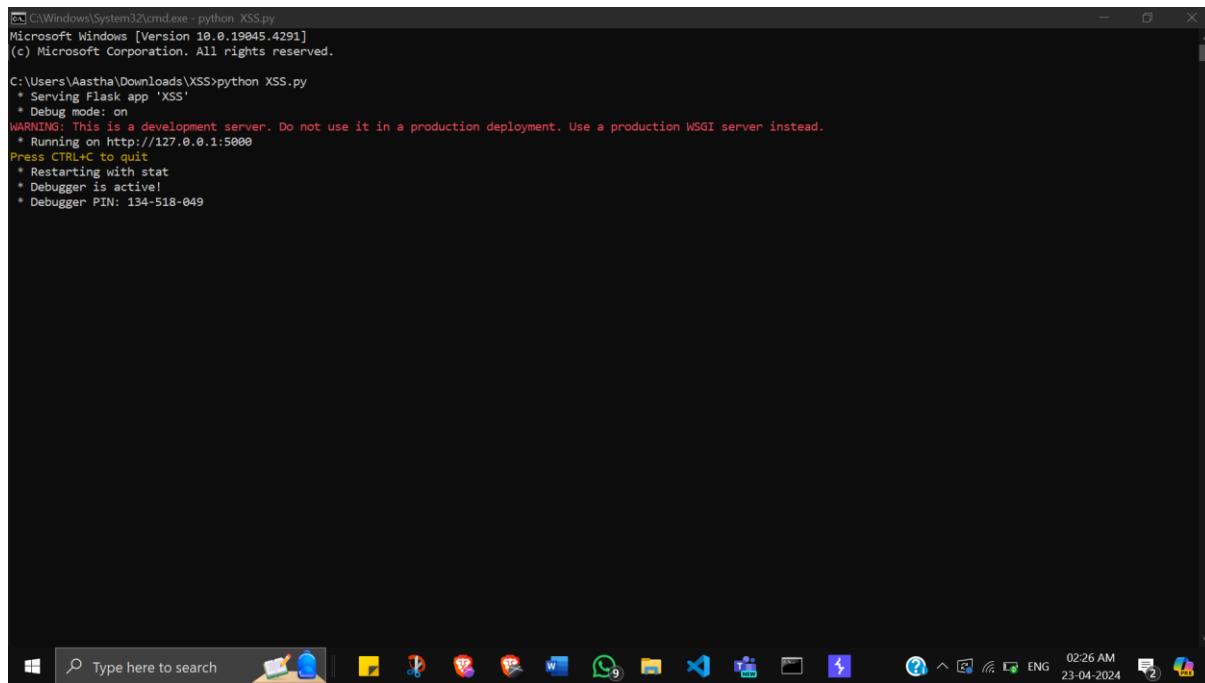

Setup:

Our primary tool for this experiment is Burp Suite, a powerful web application testing toolkit widely used by cybersecurity professionals and ethical hackers. Burp Suite helps in identifying security vulnerabilities, understanding how they can be exploited, and recommending preventive measures.

Flask app made by me

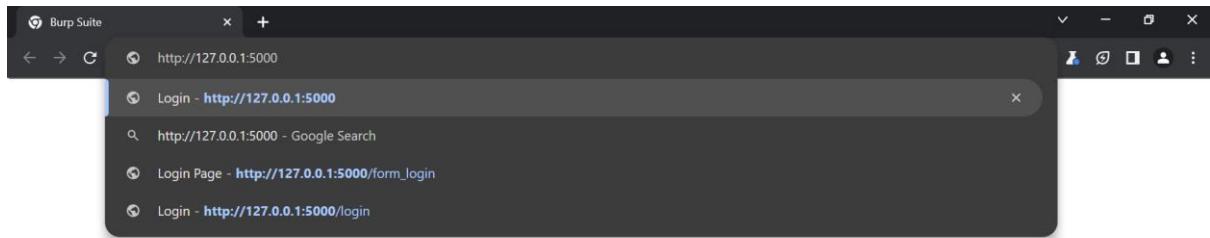

Experiment Steps:

Step 1: First, ensure that Burp is correctly configured with your browser. With intercept turned off in the Proxy "Intercept" tab, visit the web application you are testing in your browser.

```
C:\Windows\System32\cmd.exe - python XSS.py
Microsoft Windows [Version 10.0.19045.4291]
(c) Microsoft Corporation. All rights reserved.

C:\Users\Aastha\Downloads\xSS>python XSS.py
 * Serving Flask app 'XSS'
 * Debug mode: on
WARNING: This is a development server. Do not use it in a production deployment. Use a production WSGI server instead.
 * Running on http://127.0.0.1:5000
Press CTRL+C to quit
 * Restarting with stat
 * Debugger is active!
 * Debugger PIN: 134-518-049
```

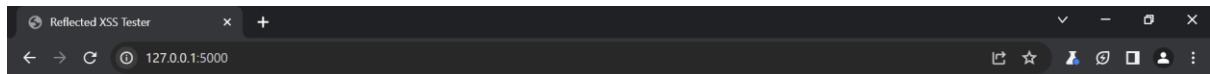

Reflected XSS Tester

Input String:

Step 2: Return to Burp. In the Proxy "Intercept" tab, ensure "Intercept is on". A simple payload such as <s> can often be used to check for issues. In this example we have used a command that attempts to perform a pop up in our browser.

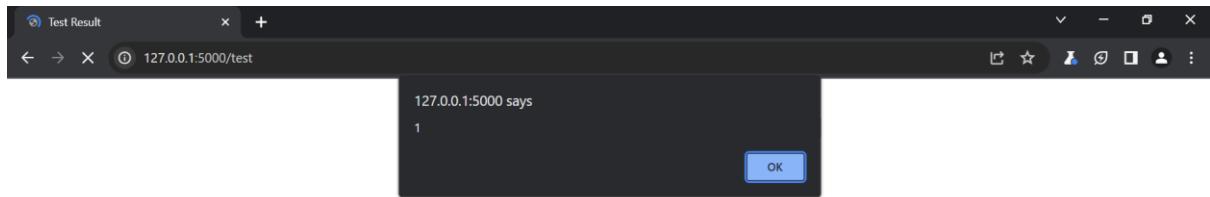

Step 3: Type in “<script>alert (1)</script>” in the input box. A pop up message will immediately show implying scripting is being used.

Reflected XSS Tester

Input String:
<script>alert(1)</script>

Test

Observation and Results:

1. The experiment underscores the critical importance of implementing robust input validation mechanisms to mitigate the risk of SQL injection attacks.
2. Developers should utilize secure coding practices, such as parameterized queries and input sanitization, to prevent SQL injection vulnerabilities in their applications.
3. Security professionals should regularly assess and test web applications for SQL injection vulnerabilities.

EXPERIMENT 5

Aim:

Cross Site request Forgery

Experiment Objective:

The main goal of the CSRF experiment using Burp Suite is to provide students with practical insights into the detection, exploitation, and prevention of Cross-Site Request Forgery vulnerabilities in web applications.

Introduction :

Cross-site request forgery (CSRF) is an attack which forces an end user to execute unwanted actions on a web application to which they are currently authenticated. CSRF vulnerabilities may arise when applications rely solely on HTTP cookies to identify the user that has issued a particular request. Because browsers automatically add cookies to requests regardless of the request's origin, it may be possible for an attacker to create a malicious web site that forges a cross-domain request to the vulnerable application.

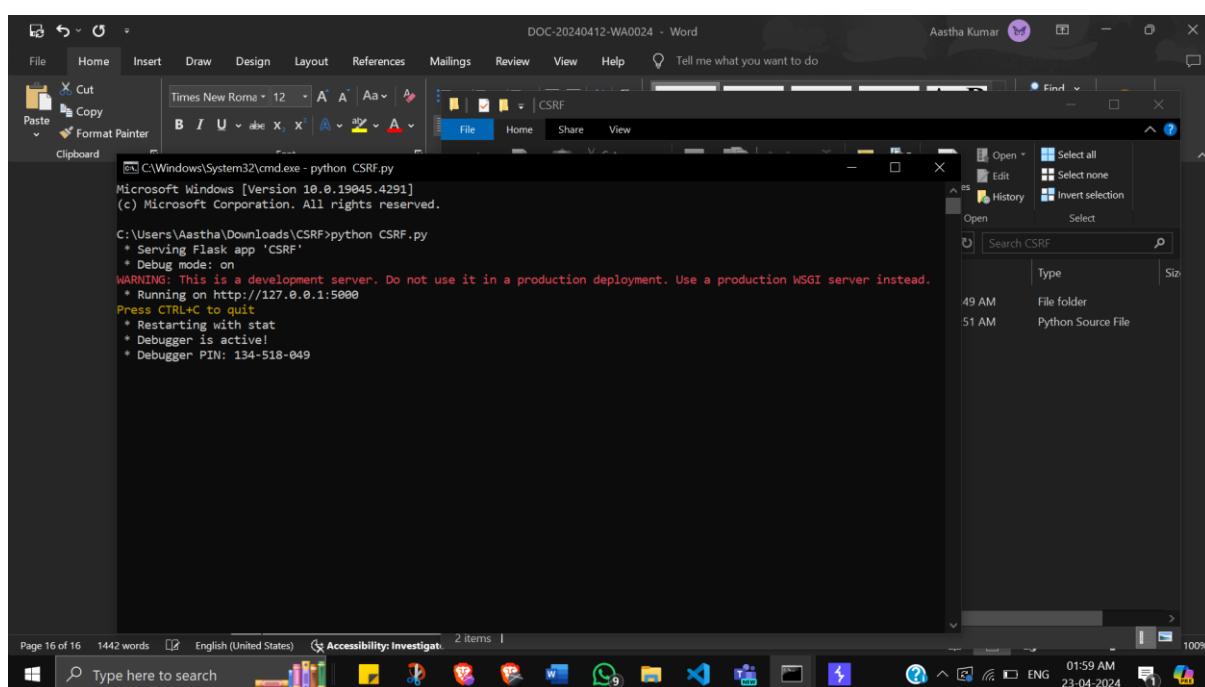

Setup:

Burp Suite

Flask App created by me (login page)

Experiment Steps:

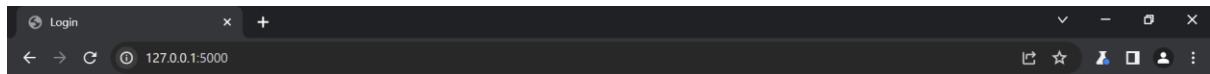

Step 1: To manually test for CSRF vulnerabilities, first, ensure that Burp is correctly configured with your browser. In the Burp Proxy "Intercept" tab, ensure "Intercept is off". Visit the web application you are testing in your browser.

The screenshot shows a Microsoft Word document window titled 'DOC-20240412-WA0024 - Word'. The content of the document is a command-line session from a Windows terminal. The session starts with 'cmd.exe - python CSRF.py' and shows the output of a Flask application running on port 5000. It includes a warning about using it in production, information about the debugger, and a debugger PIN. The Word document interface is visible, including the ribbon, toolbars, and status bar at the bottom.

```
C:\Windows\System32\cmd.exe - python CSRF.py
Microsoft Windows [Version 10.0.19045.4291]
(c) Microsoft Corporation. All rights reserved.

C:\Users\Aastha\Downloads\CSRF>python CSRF.py
* Serving Flask app "CSRF"
* Debug mode: on

Step 4: In the "CSRF PoC generator" window you should alter the value of the user supplied input. In this example we will email from aastha@gmail.com to sakib@gmail.com

Request to: http://127.0.0.1:5000

```

1 POST /login HTTP/1.1
2 Host: 127.0.0.1:5000
3 Content-Length: 34
4 Cache-Control: max-age=0
5 sec-ch-ua: "Chromium";v="121", "Not A(Brand";v="99"
6 sec-ch-ua-mobile: 70
7 sec-ch-ua-platform: "Windows"
8 Upgrade-Insecure-Requests: 1
9 Origin: http://127.0.0.1:5000
10 Content-Type: application/x-www-form-urlencoded
11 User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.45.2023.12.1.3 Chrome/121.0.0.0 Safari/537.45.2023.12.1.3
12 Accept: text/html,application/xhtml+xml,application/xml;q=0.9
13 Sec-Fetch-Site: same-origin
14 Sec-Fetch-Mode: navigate
15 Sec-Fetch-User: none
16 Sec-Fetch-Dest: document
17 Referer: http://127.0.0.1:5000/
18 Accept-Encoding: gzip, deflate, br
19 Accept-Language: en-US,en;q=0.9
20 Connection: close
21
22 email=sakib@gmail.com&password=

```

Step 5: Select “test in browser”. A dialog box will appear with a link. Copy it.

Show response in browser

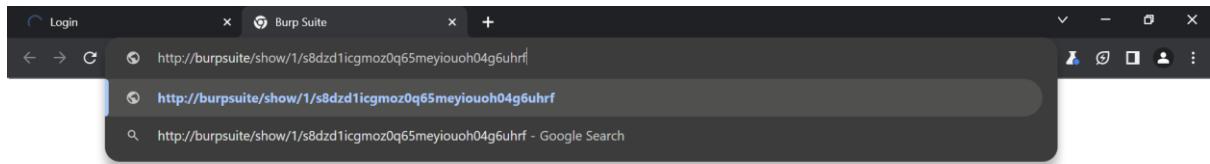

To show this response in your browser, copy the URL below and paste into a browser that is configured to use Burp as its proxy.

http://burpsuite/show/1/s8d2d1cgmzoq05meyiouh04g6uhrf

Copy

In future, just copy the URL and don't show this dialog

Step 6: In the Proxy "Intercept" tab, ensure "Intercept is off". Paste the URL in the same browser.

Step 7: Dependent on the CSRF PoC options you may need to submit the request or it may be submitted automatically. In this case we are submitting the request manually.

Step 8: If the attack has been successful and the account information has been successfully changed, this serves as an initial check to verify whether the attack is plausible.

EXPERIMENT 6

Aim:

The aim of this experiment is to demonstrate the use of encryption and digital signatures for secure communication using Kleopatra software,

Experiment Objective:

The objective of this experiment is to:

1. Encrypt a message using Kleopatra with a chosen key and send it to a friend for decryption.
2. Encrypt a message and sign it using Kleopatra, then send it to a friend for verification of the signature.

Introduction :

In today's digital world, ensuring the confidentiality and integrity of communication is crucial. Encryption and digital signatures are essential techniques for achieving these goals. Encryption protects the content of a message from unauthorized access, while digital signatures verify the authenticity and integrity of the sender.

Kleopatra is an open-source encryption software that provides a user-friendly interface for managing encryption keys, encrypting and decrypting messages, and creating digital signatures. In this experiment, we will use Kleopatra to encrypt messages and demonstrate secure communication between two parties.

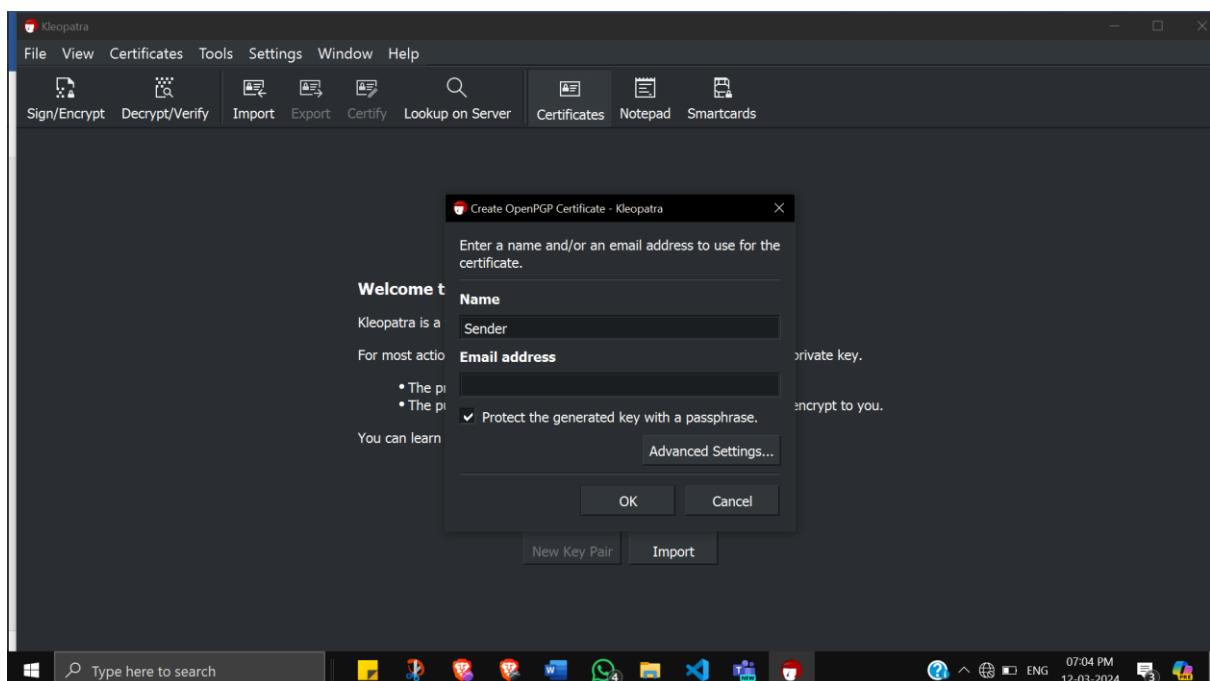

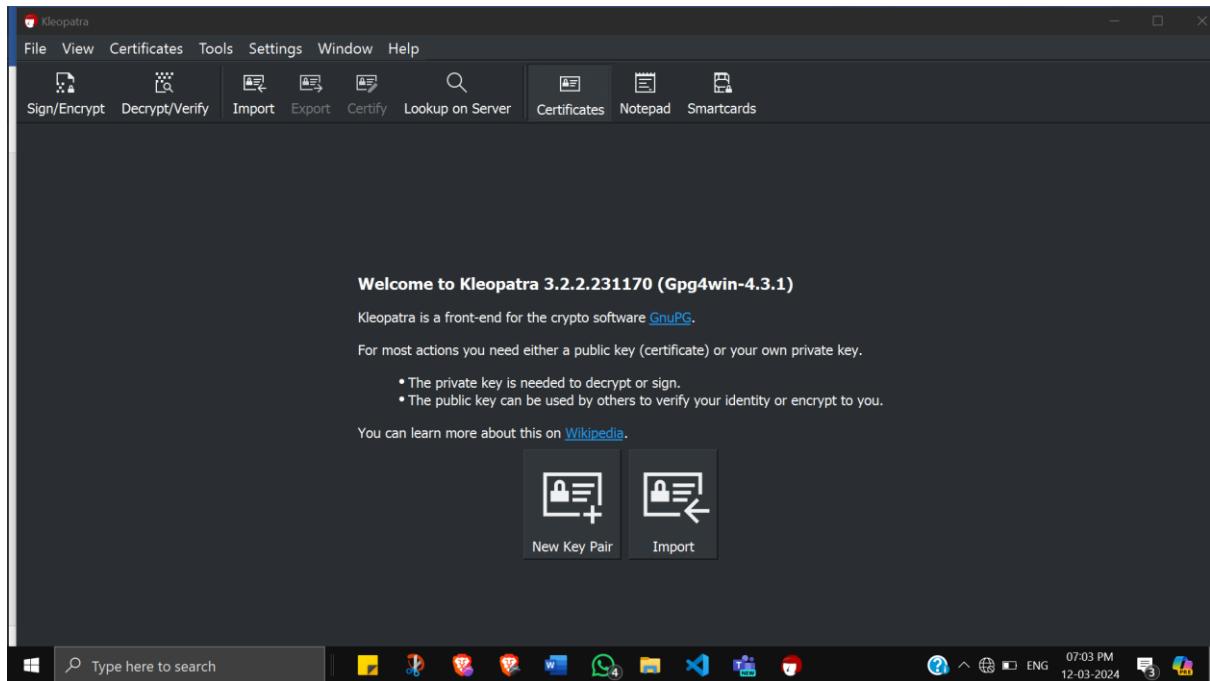

Setup:

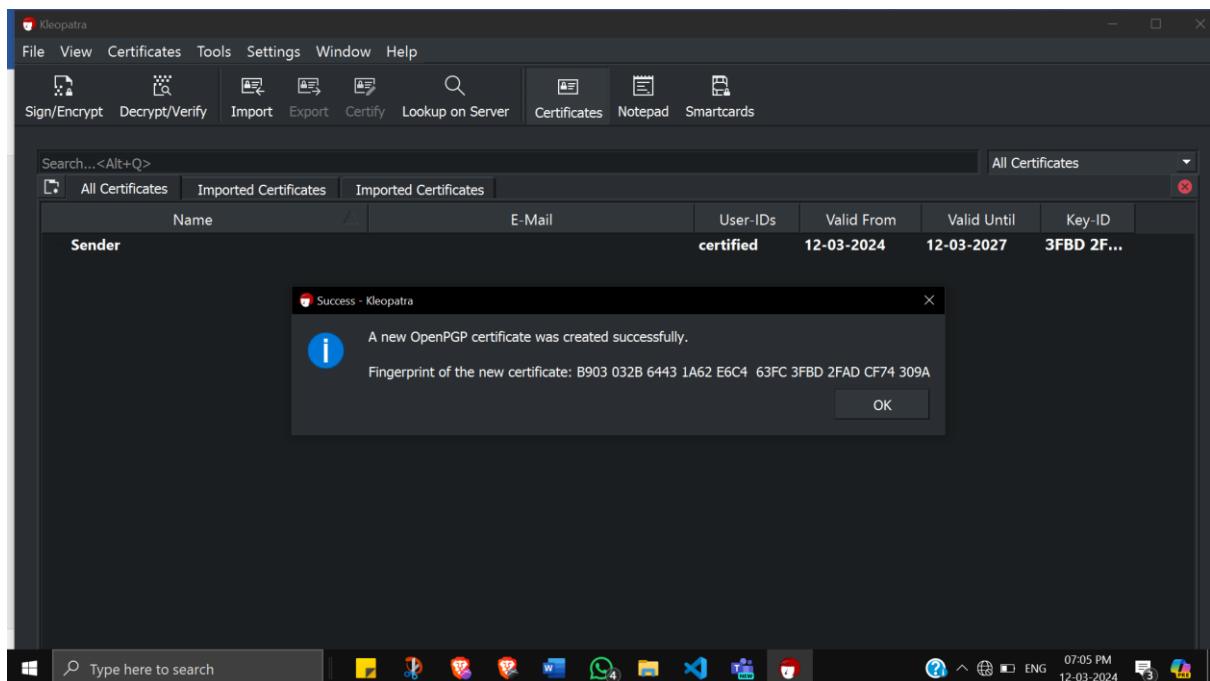

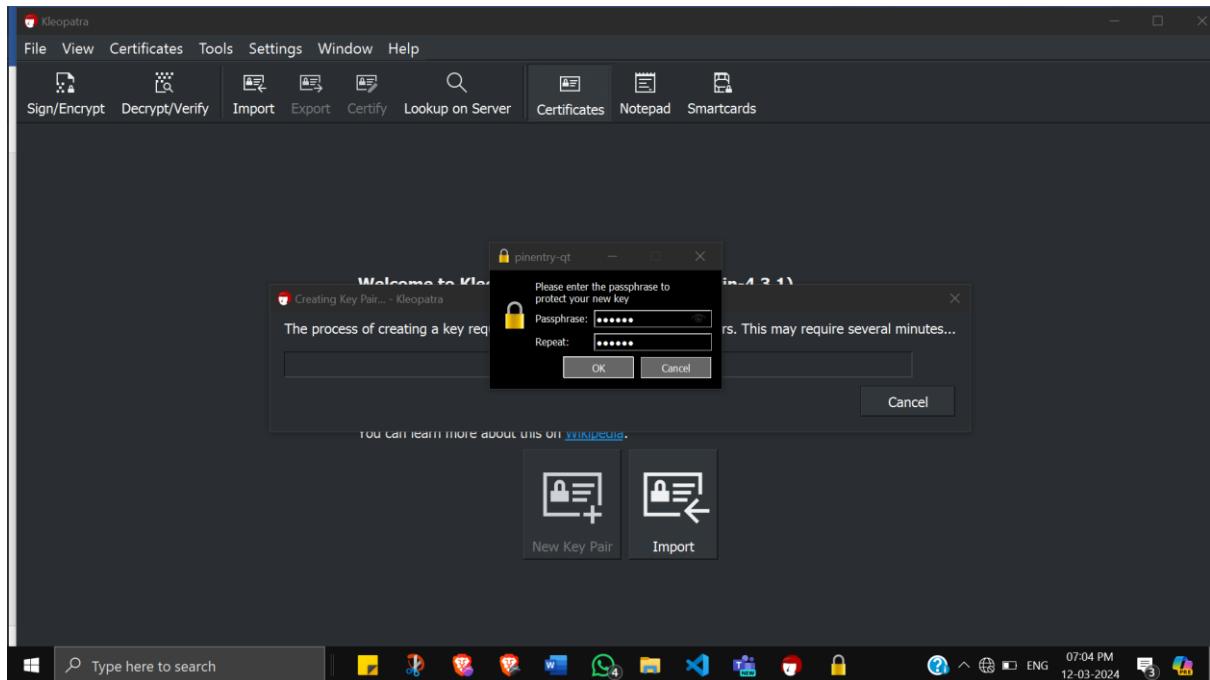

- Kleopatra: Kleopatra is an encryption software that is part of the GNU Privacy Guard (GnuPG) suite. It is available for Windows and Linux operating systems and can be downloaded from the Gpg4win website for Windows users or installed through package managers on Linux systems.
 - Download Kleopatra for Windows: Gpg4win website
 - Install Kleopatra following the installation instructions provided on the website.
- Email Client: You will need an email client to send encrypted messages to your friend. Popular email clients such as Microsoft Outlook, Mozilla Thunderbird, or web-based clients like Gmail can be used.
- Public Key: Obtain the public key of your friend with whom you want to communicate securely. You can import the public key into Kleopatra to encrypt messages for them.
 - Your friend should provide you with their public key, which you can import into Kleopatra.
 - In Kleopatra, go to "File" > "Import Certificates" and select the public key file provided by your friend.

Experiment Steps:

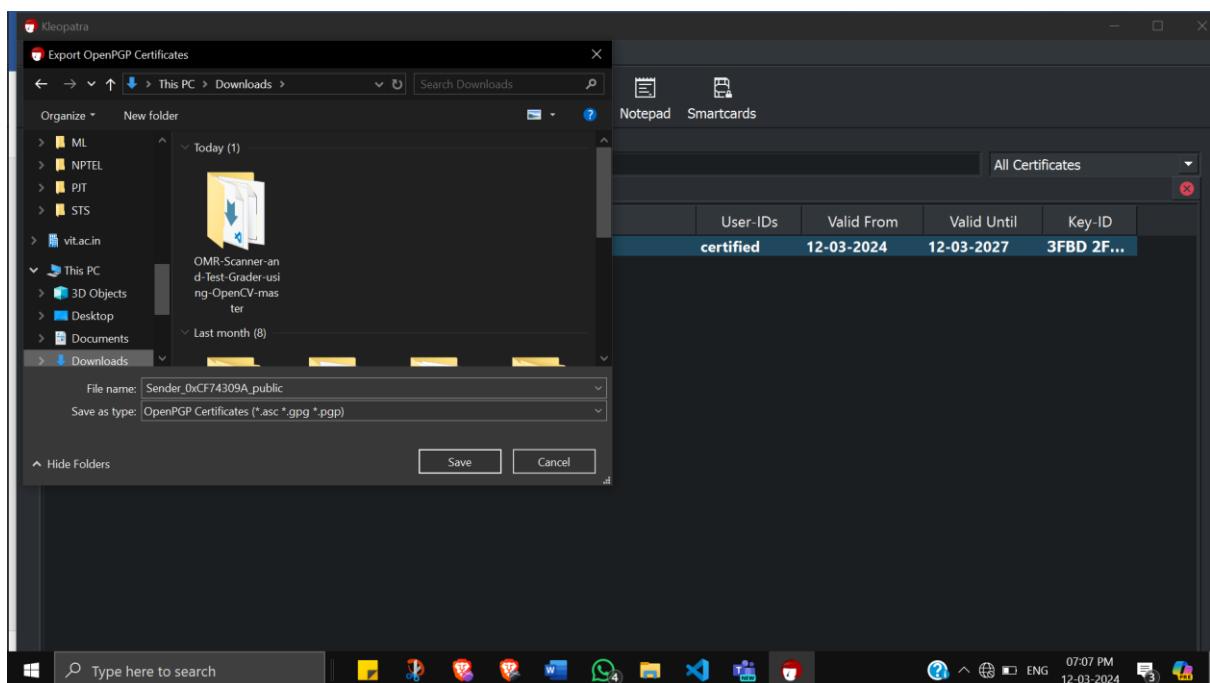

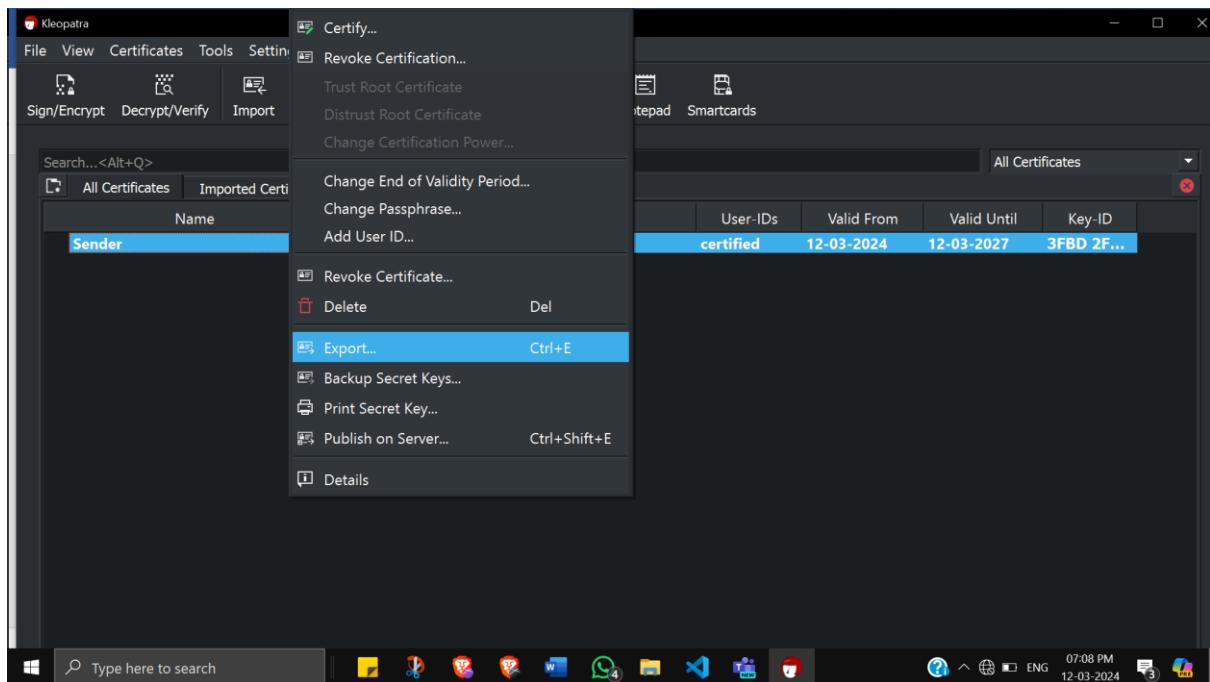

Task 1: Encrypt a message and send it to a friend using any key of your choice. They should be able to decrypt it and retrieve original message.

1. Create a new key pair for the sender's side. Enter a Name and click OK. Enter a passphrase and click OK.

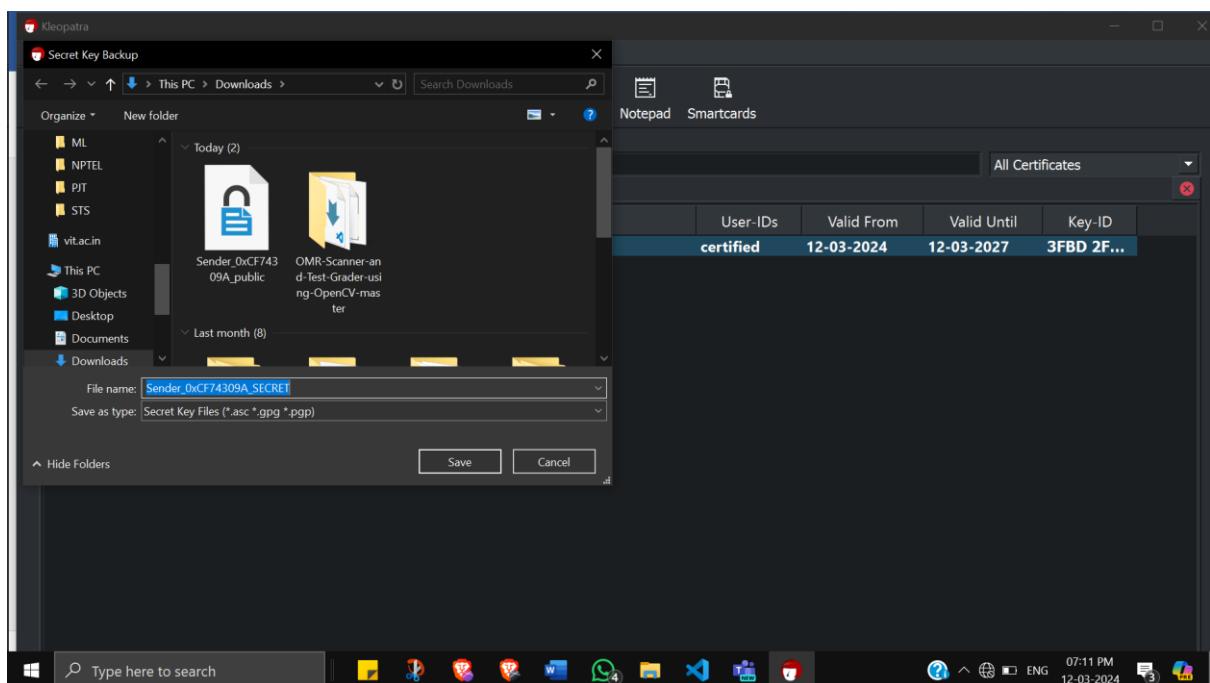

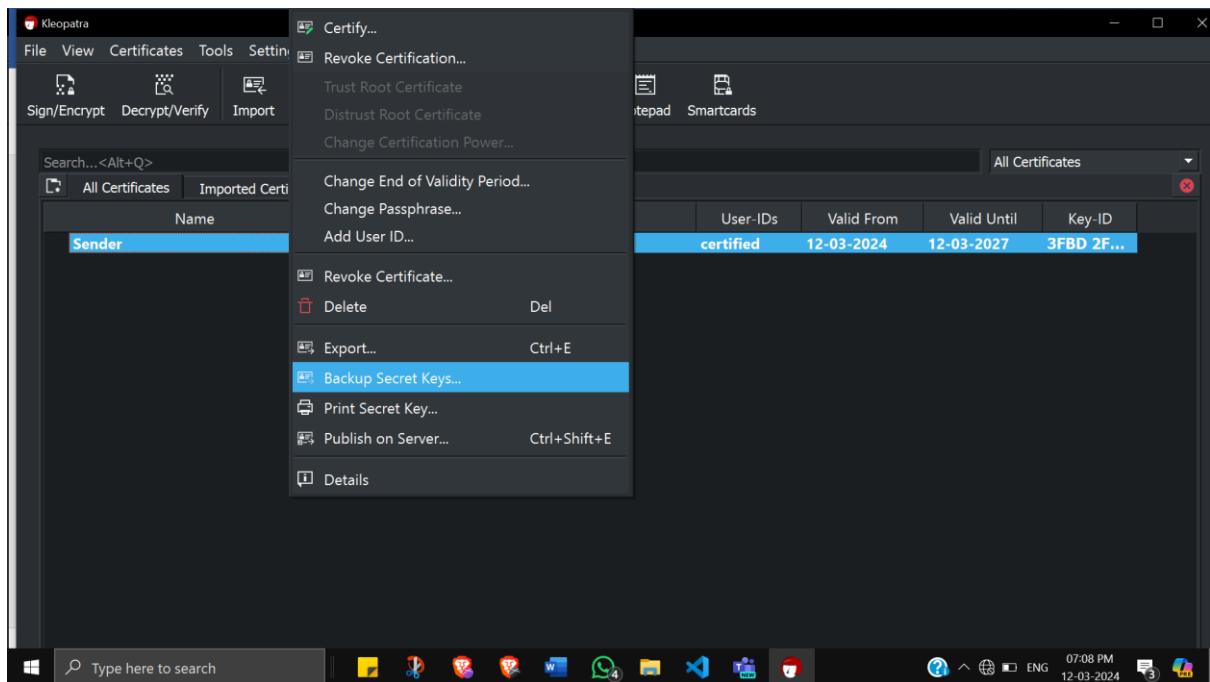

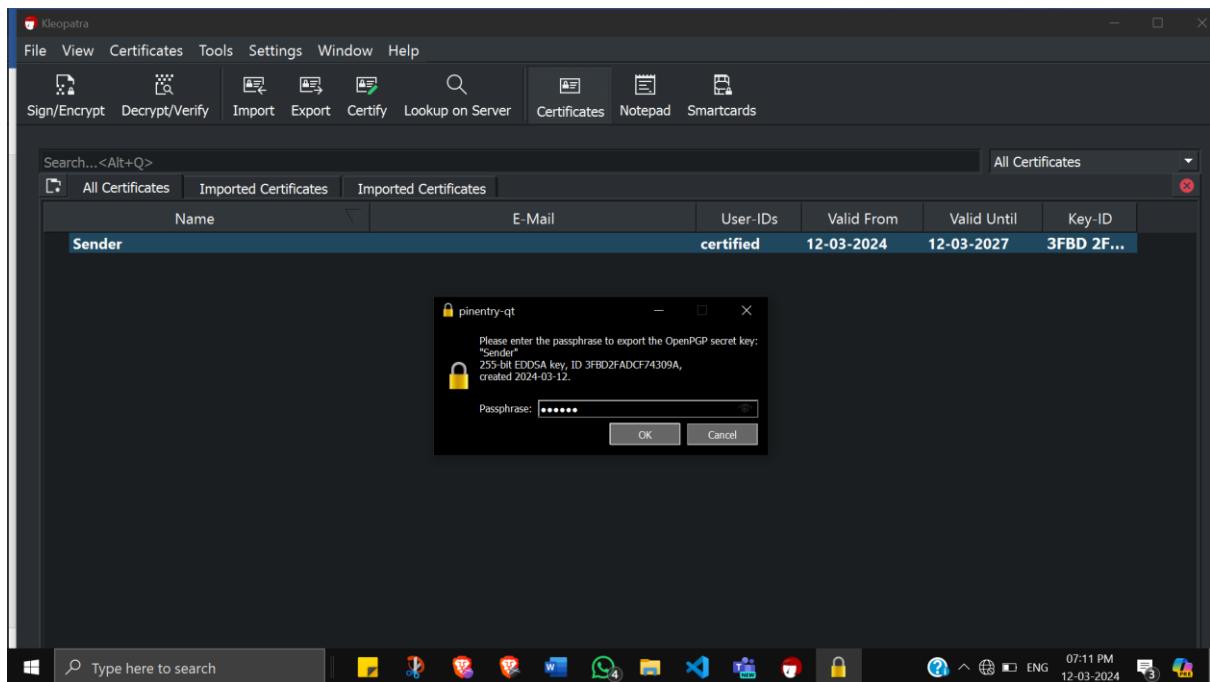

2. Right click on the freshly created certificate and select “Export”. Save the public key.

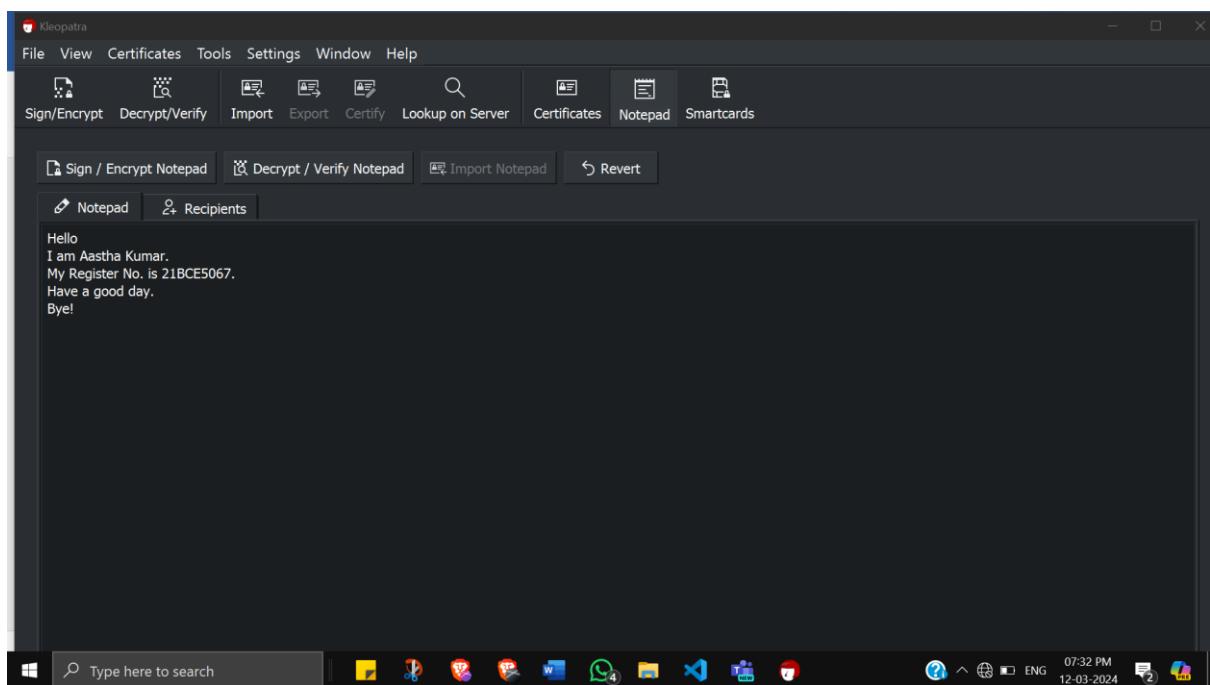

3. Right click on the freshly created certificate and select “Backup Secret Keys”. Save the private key and enter the passphrase.

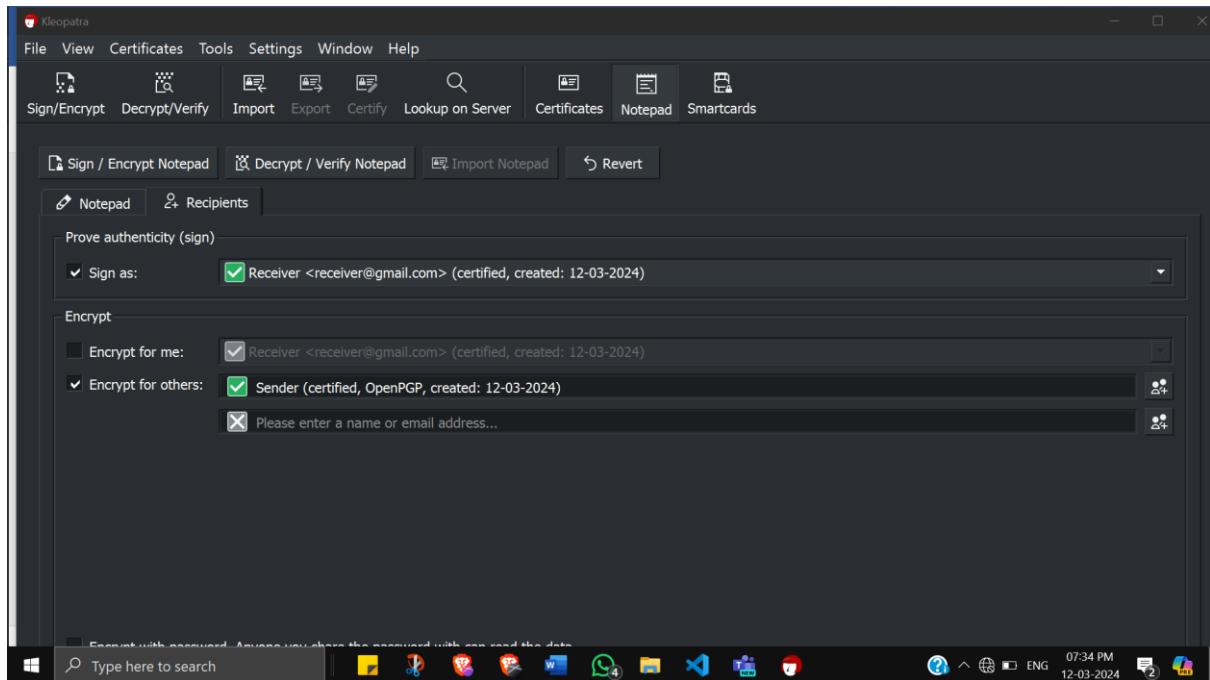

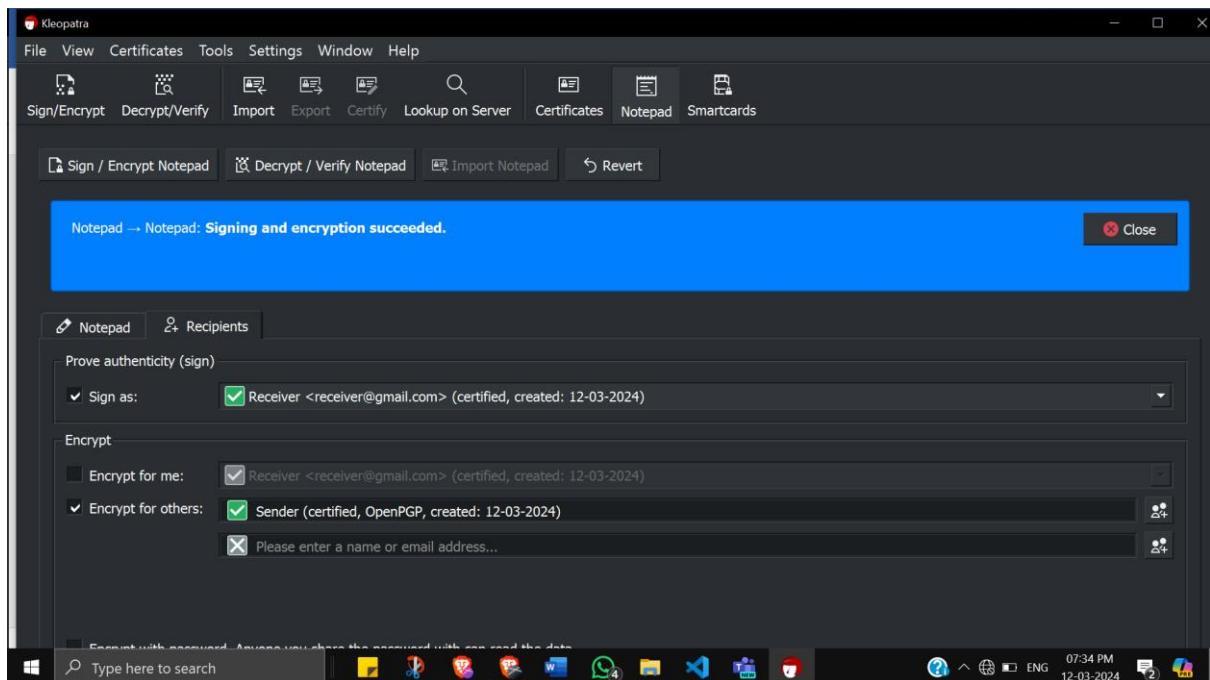

4. Go to Notepad and type in a message.

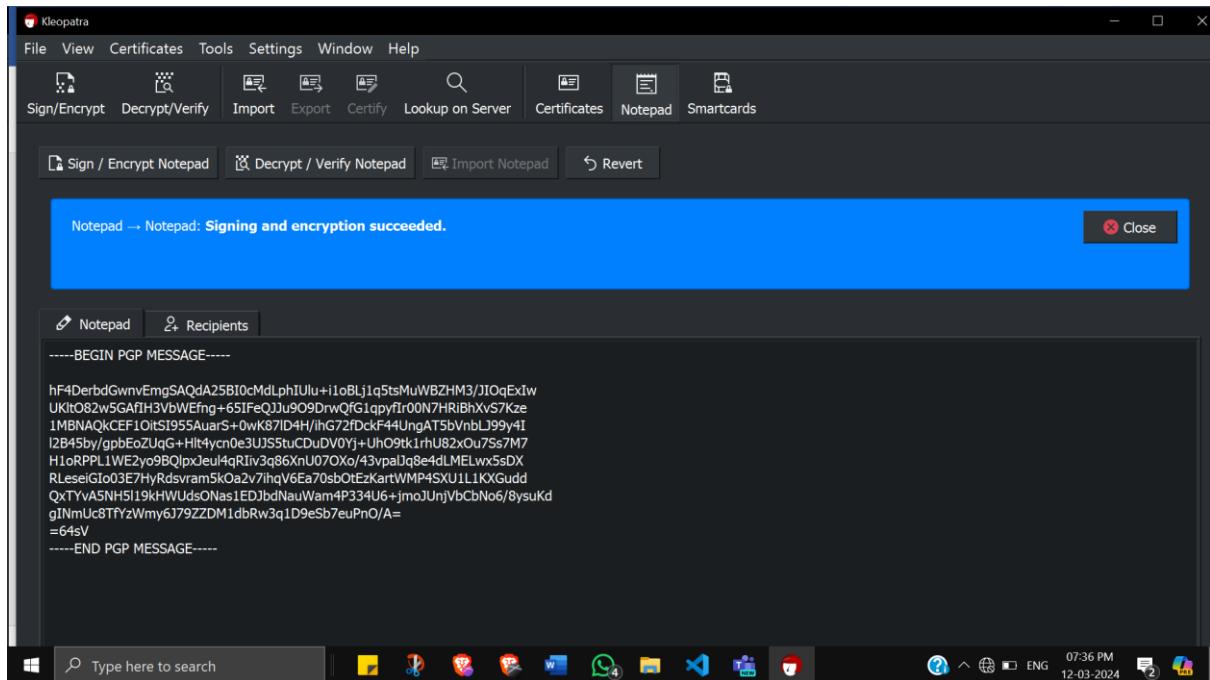

5. Under Recipients tab, select Sender beside “Encrypt for other” option and “Receiver” beside “Sign as” option.

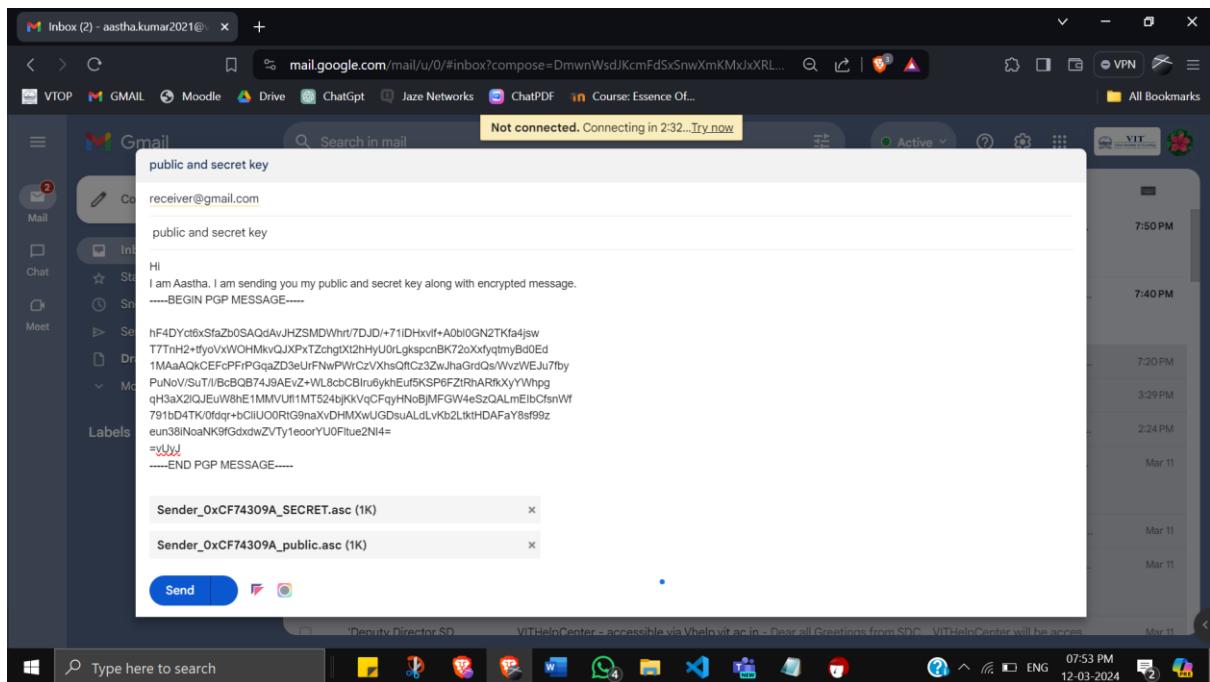

6. Encrypt the message by clicking on “Sign/Encrypt Notepad”

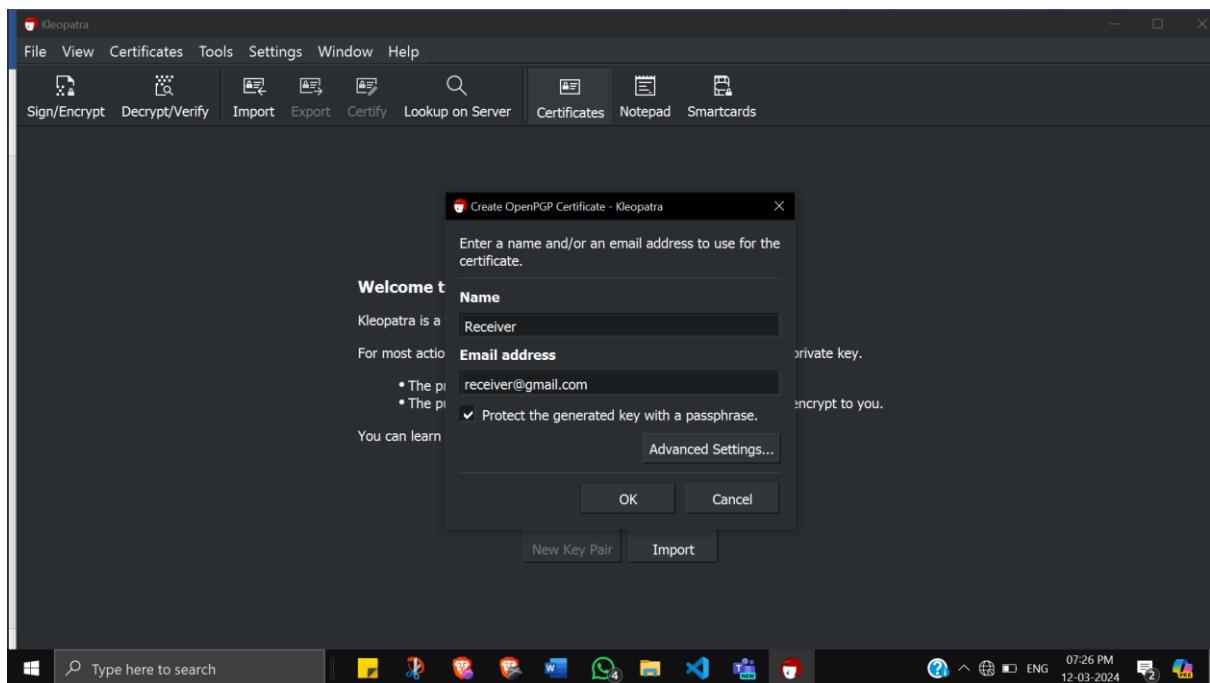

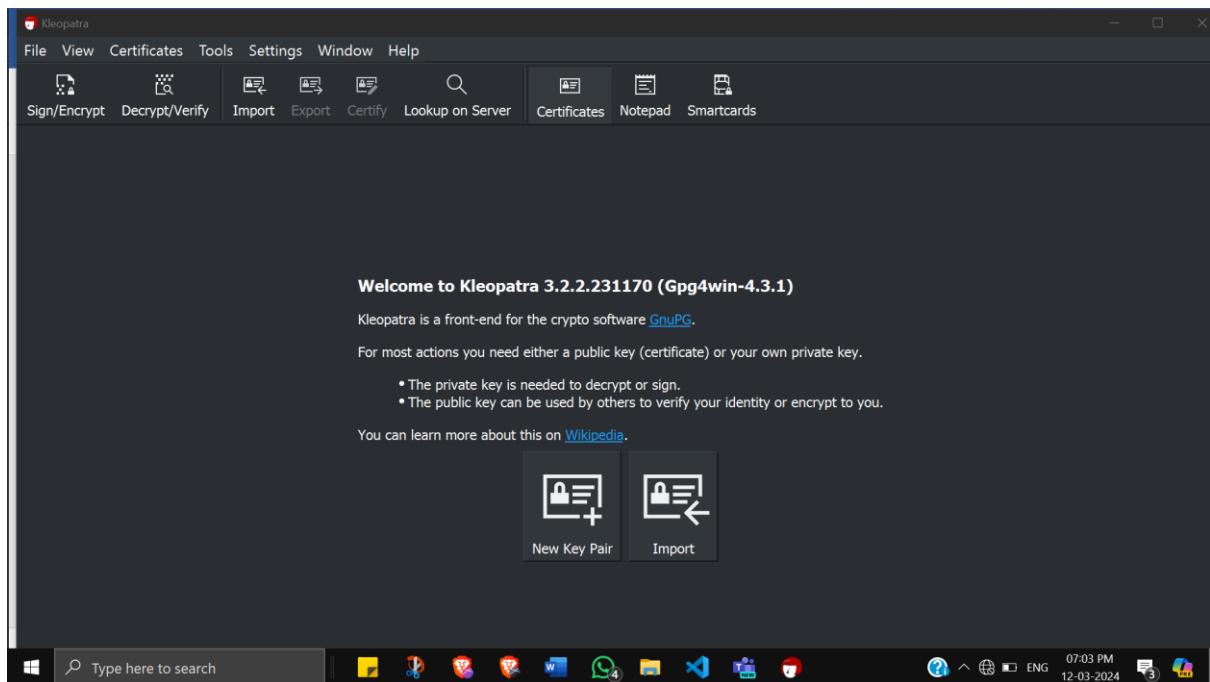

7. Go back to Notepad and now you can view the encrypted message.

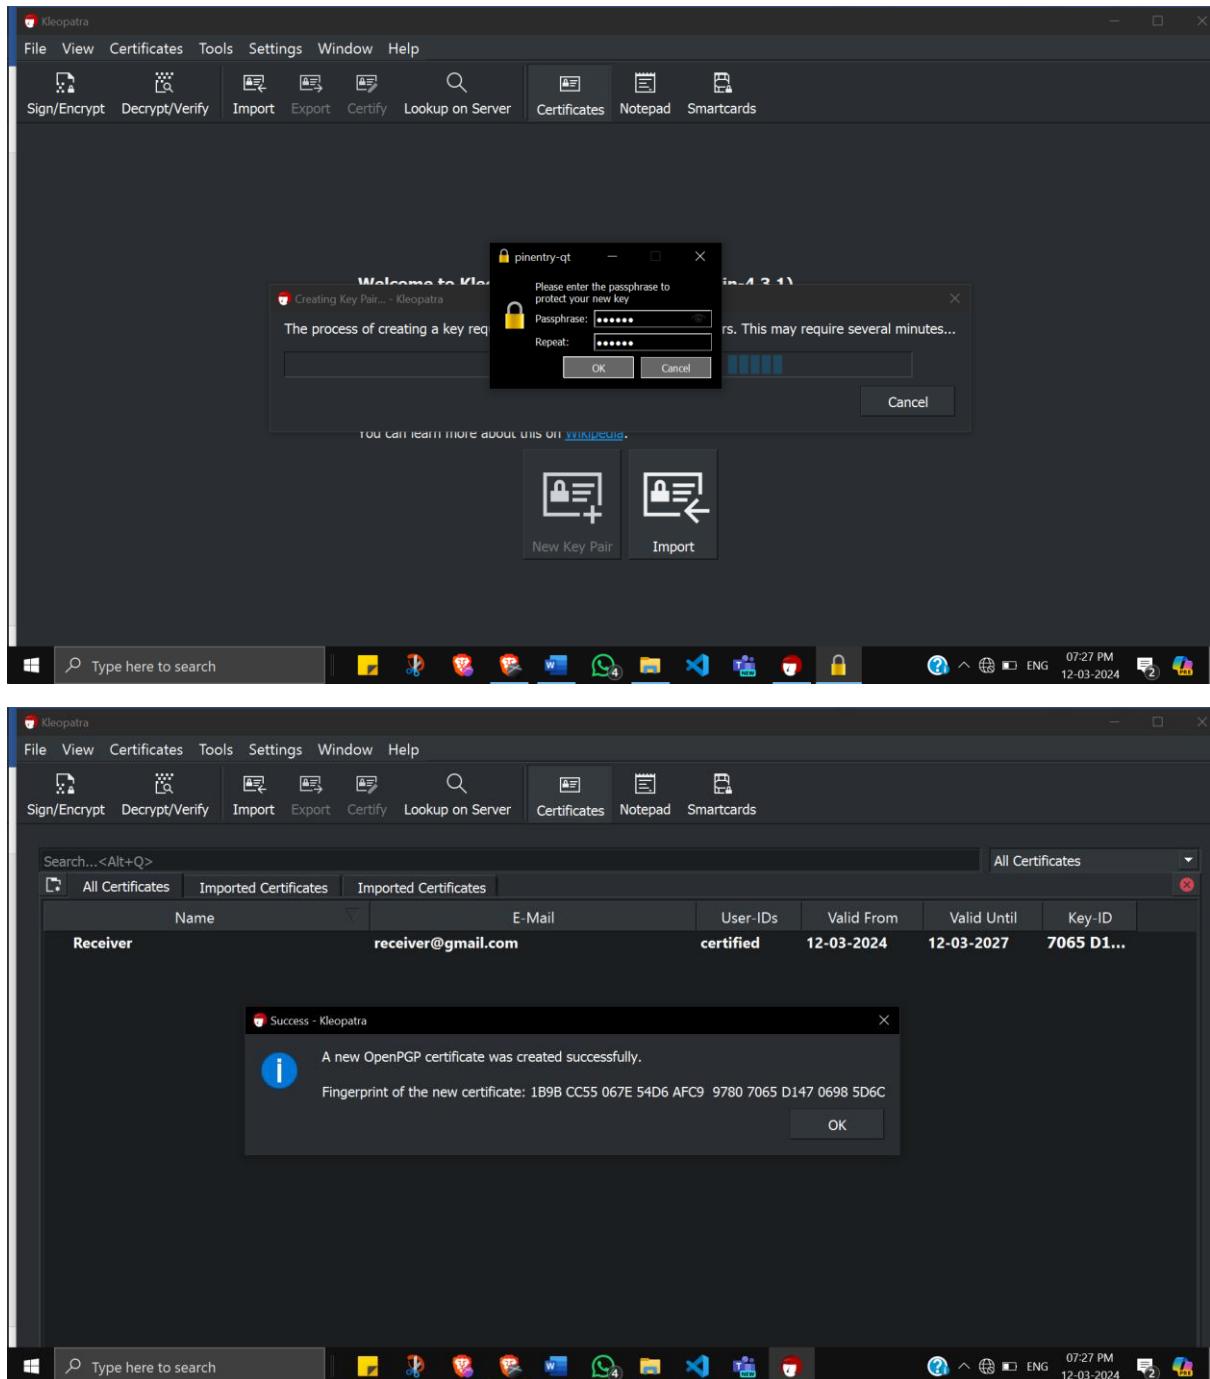

- Mail the public key and private key to the recipient along with the encrypted message.

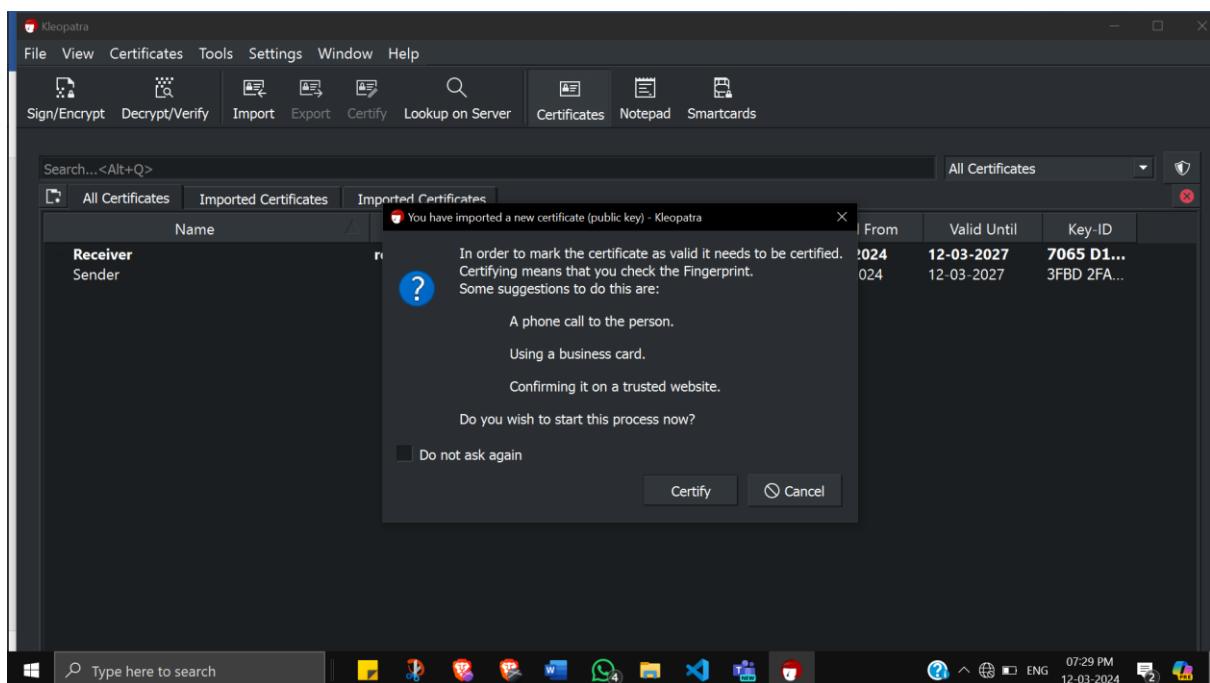

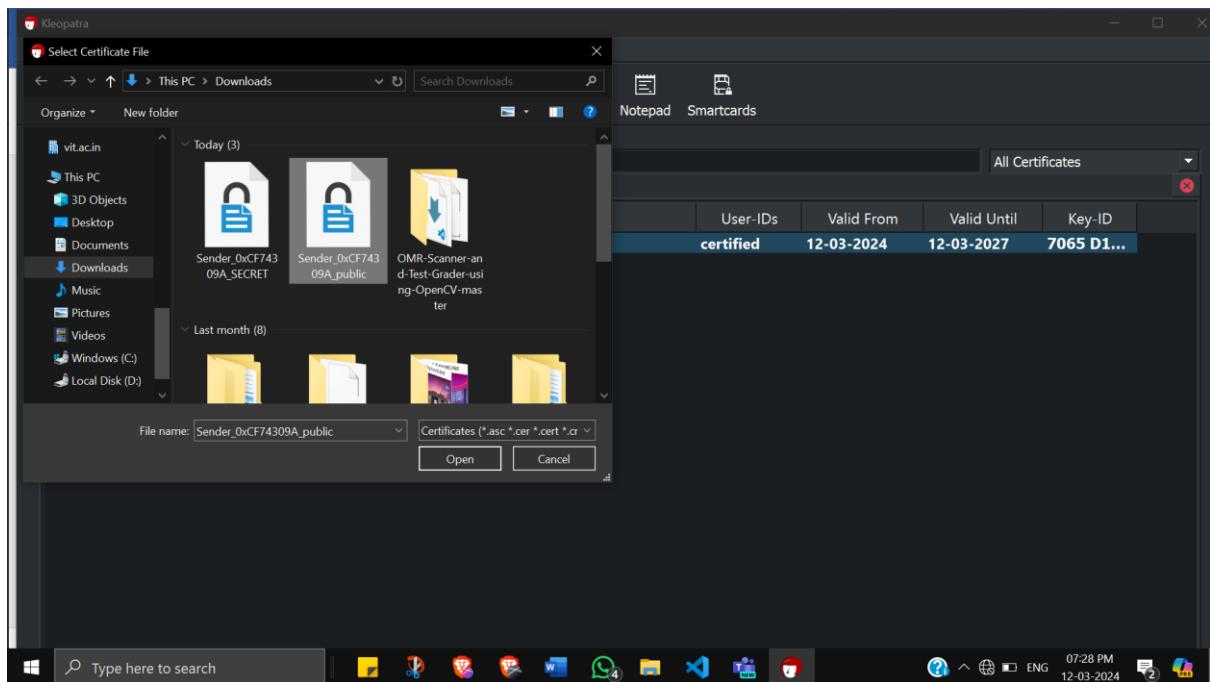

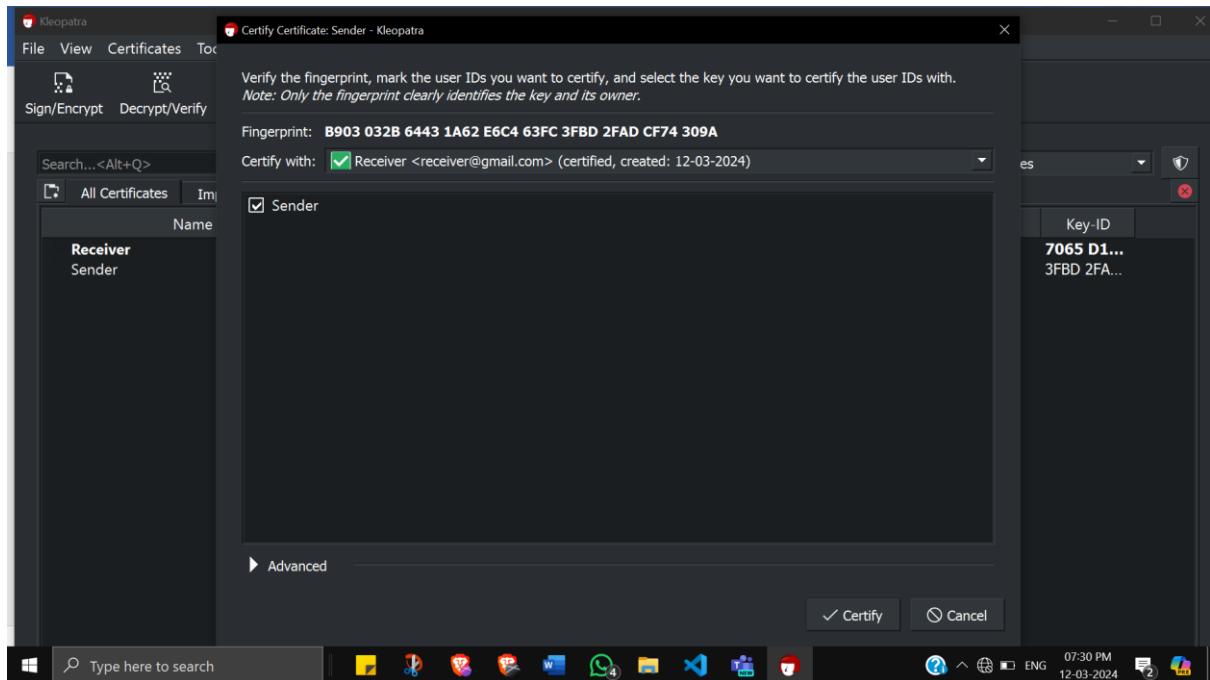

- Receiver will download the public and private key into their PC.
- Create a new key pair for the receiver's side. Enter a Name and click OK. Enter a passphrase and click OK.

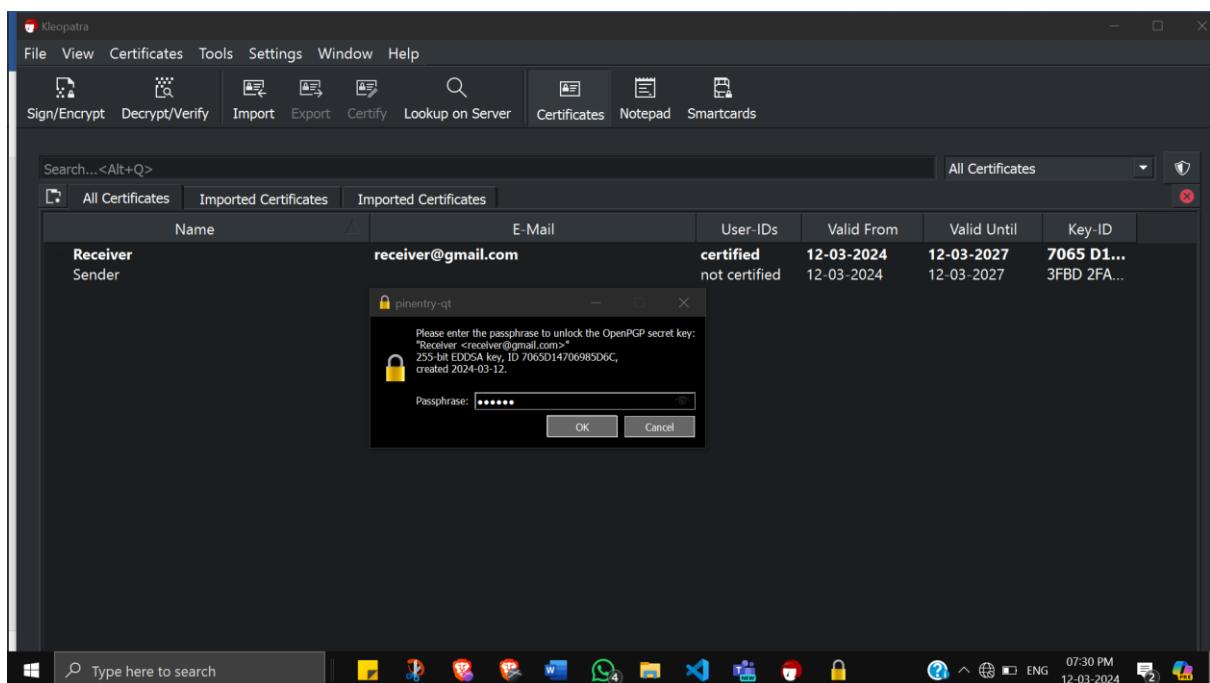

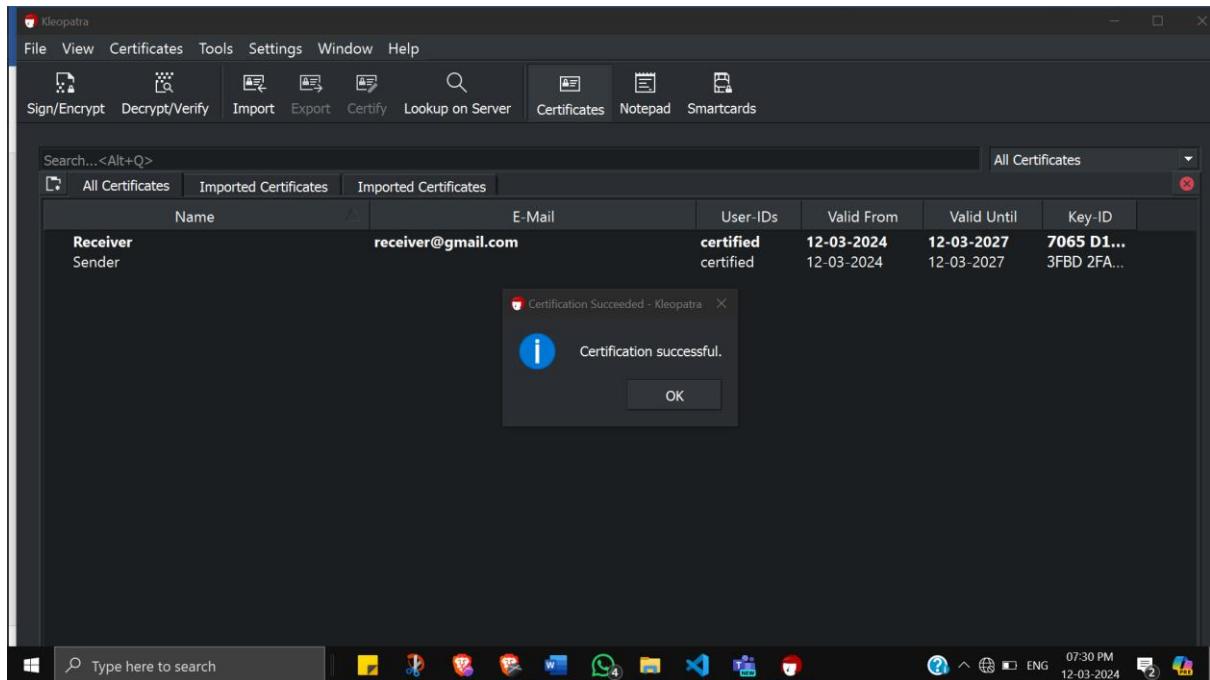

11. Click on “Import” and select public key. Click Open. Select “Certify” on the next dialogue box.

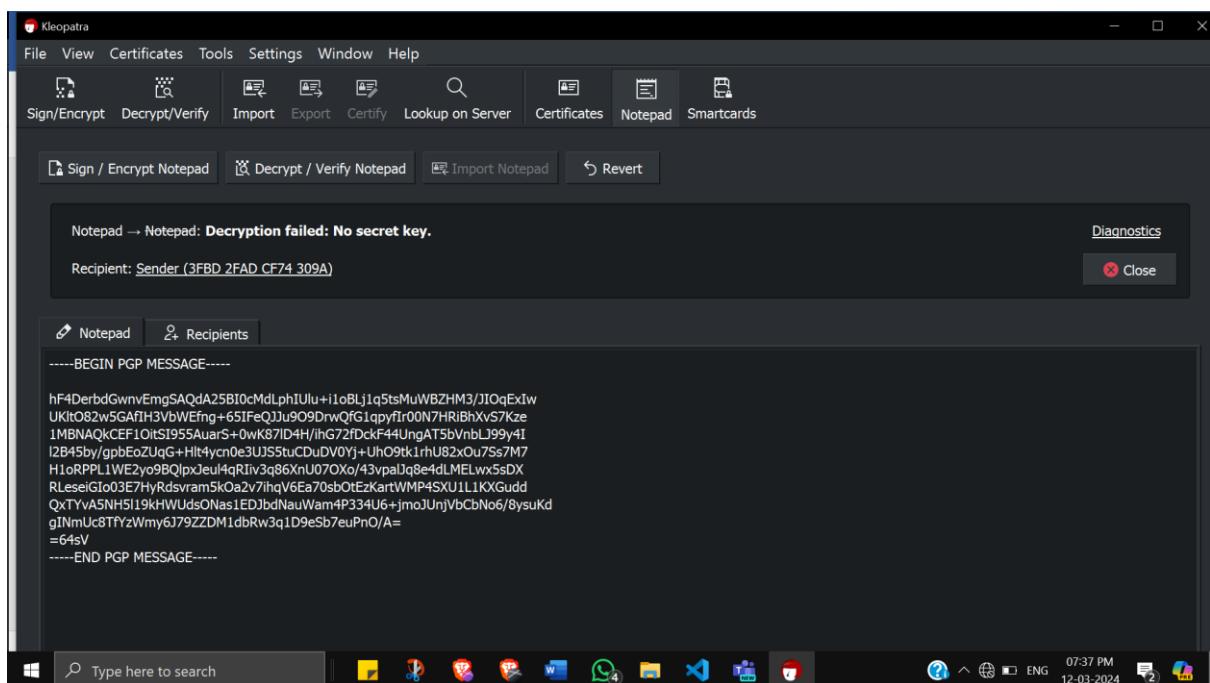

12. Enter the passphrase we had created earlier.

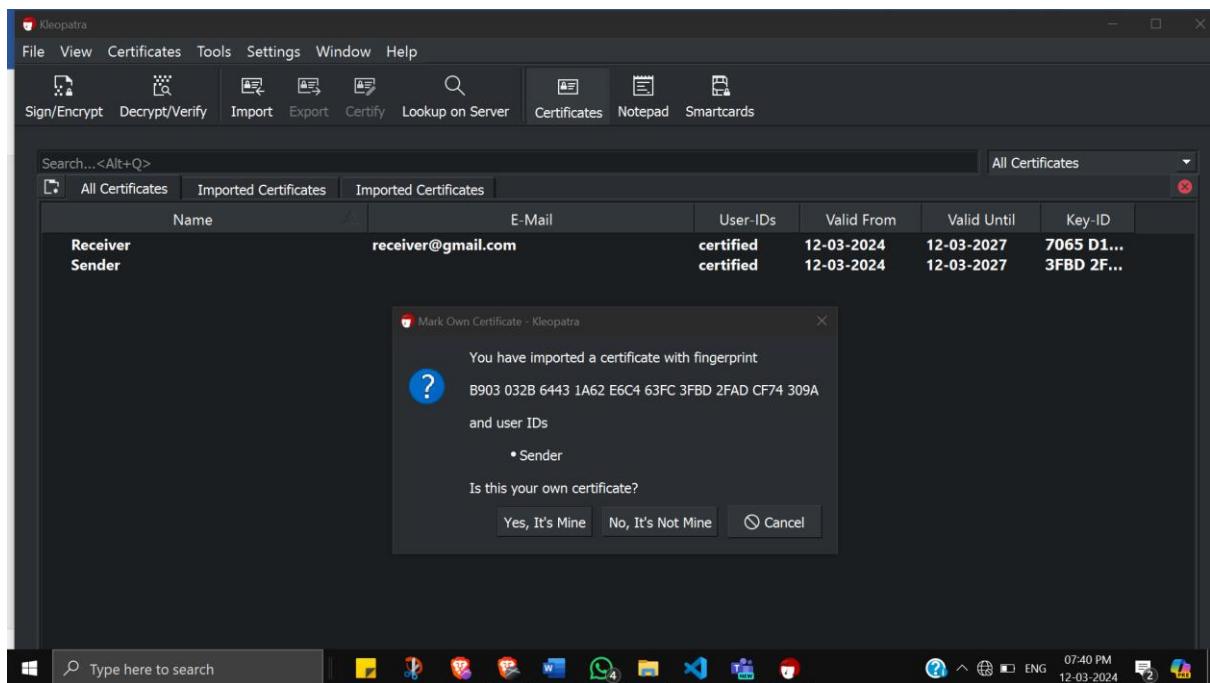

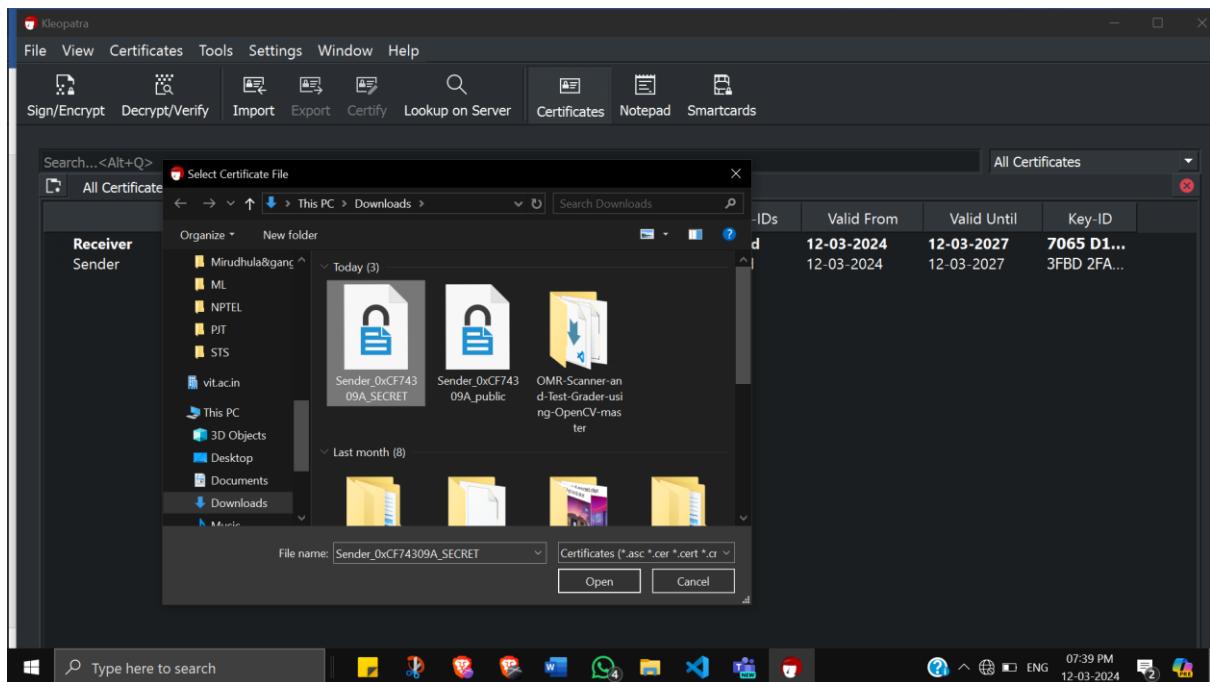

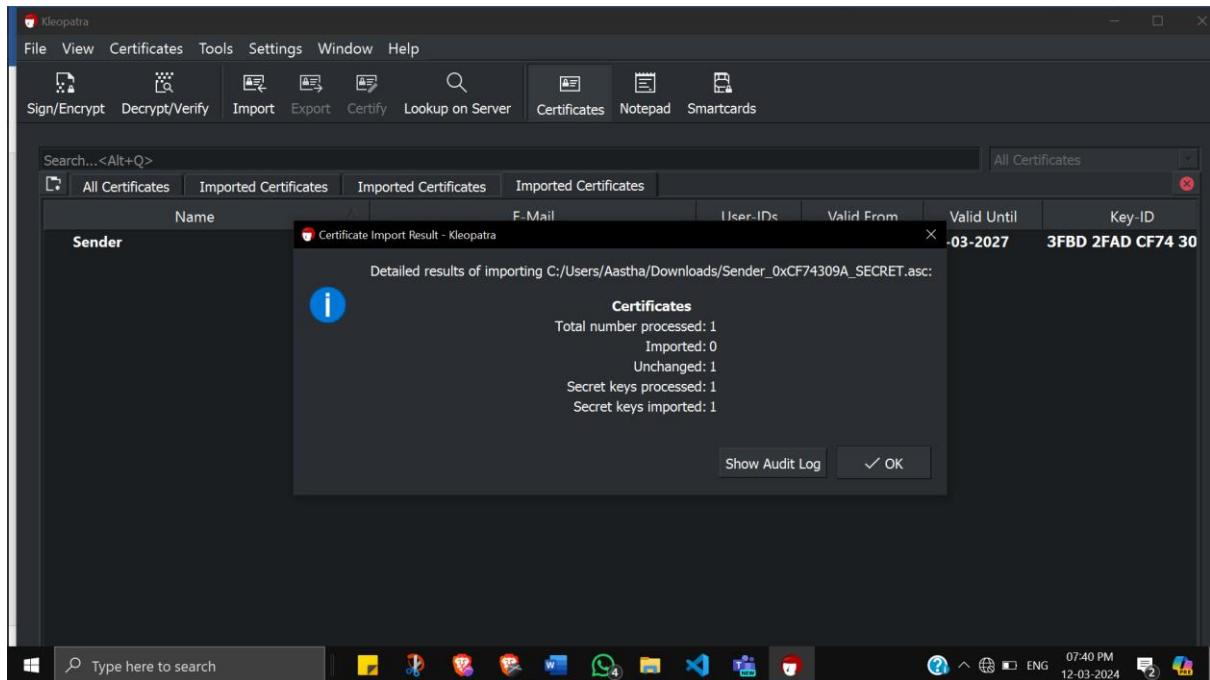

13. Now click on “Decrypt/Verify Notepad”. You will get an error.

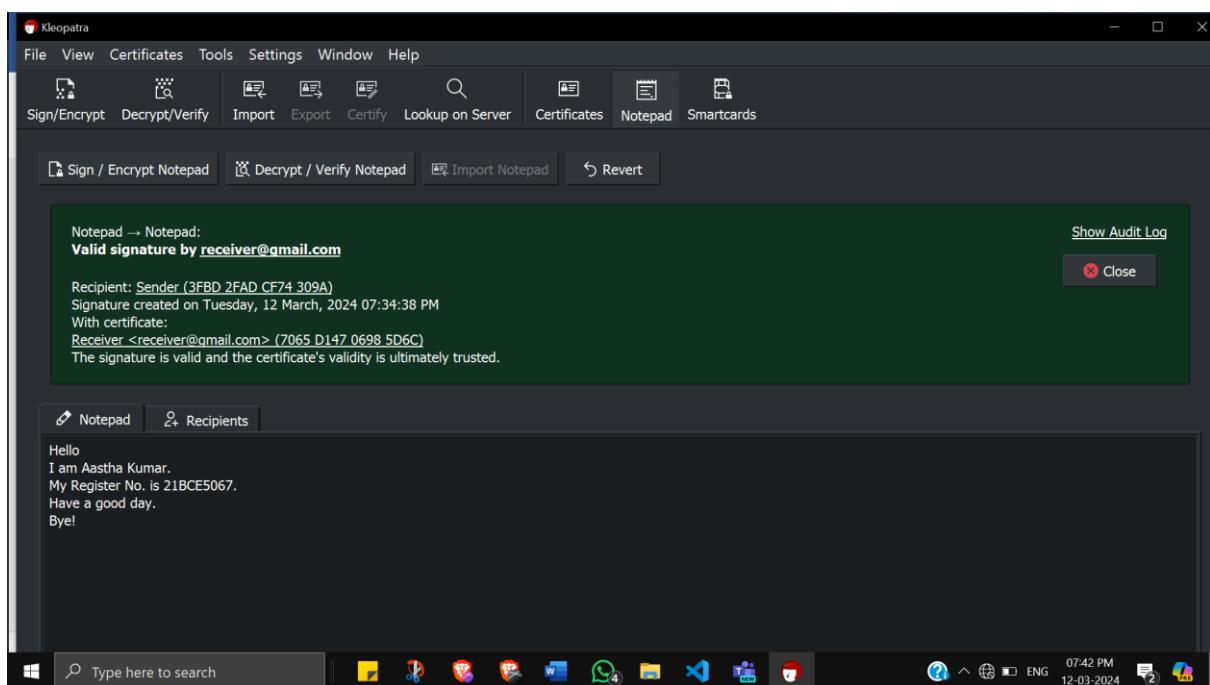

14. To tackle this error, go to Certificates and import the secret key.

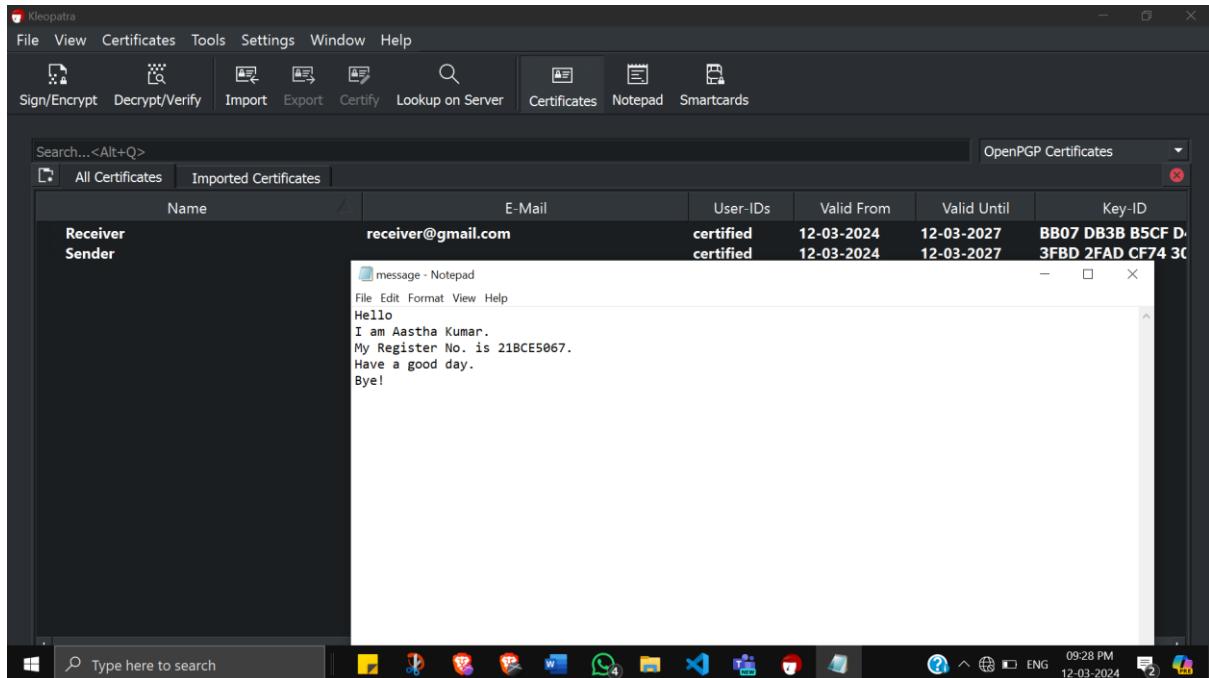

15. Now go to Notepad and click on “Decrypt/Verify Notepad”. The error is gone. The decrypted message can be viewed in the Notepad.

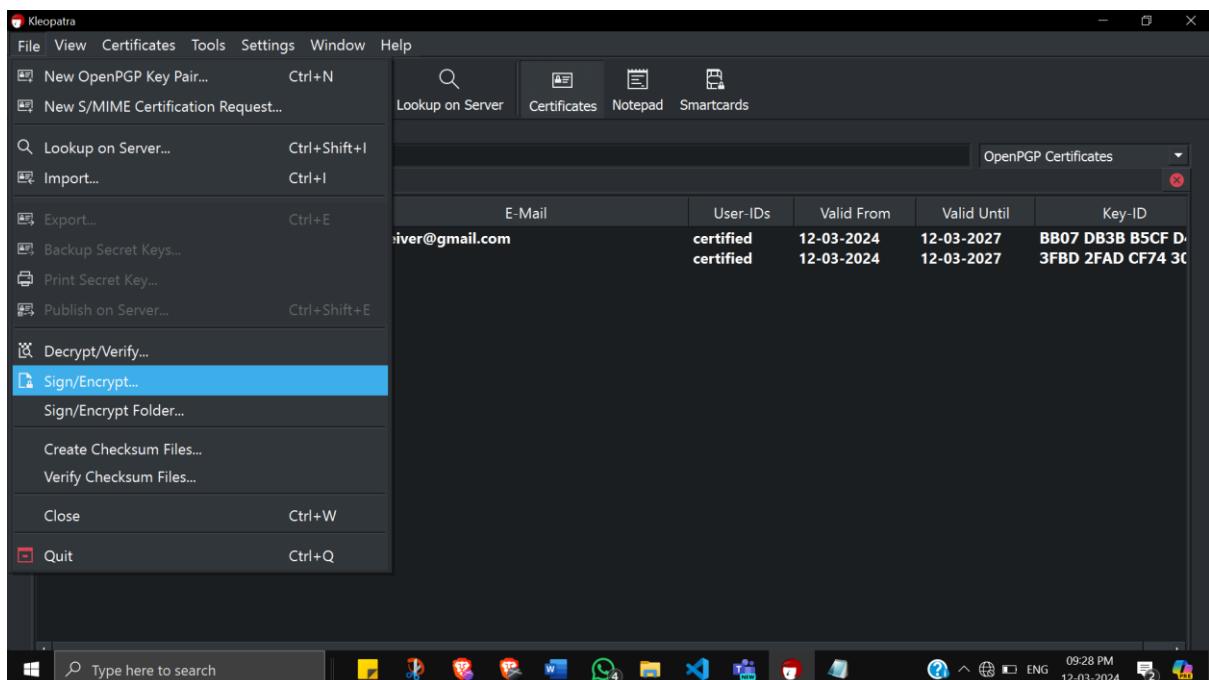

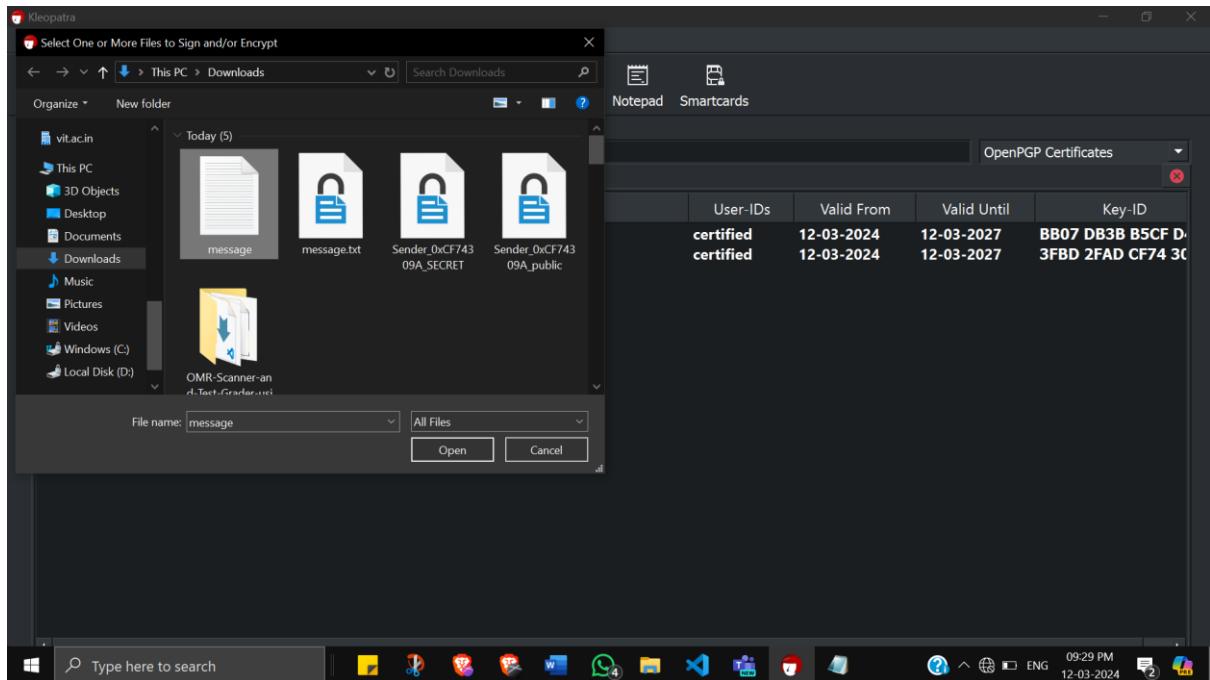

Task 2: Encrypt a message and sign it. Send it to your friend and verify the signature.

1. Open a text editor like Notepad and paste your message there. Save it as message.txt.

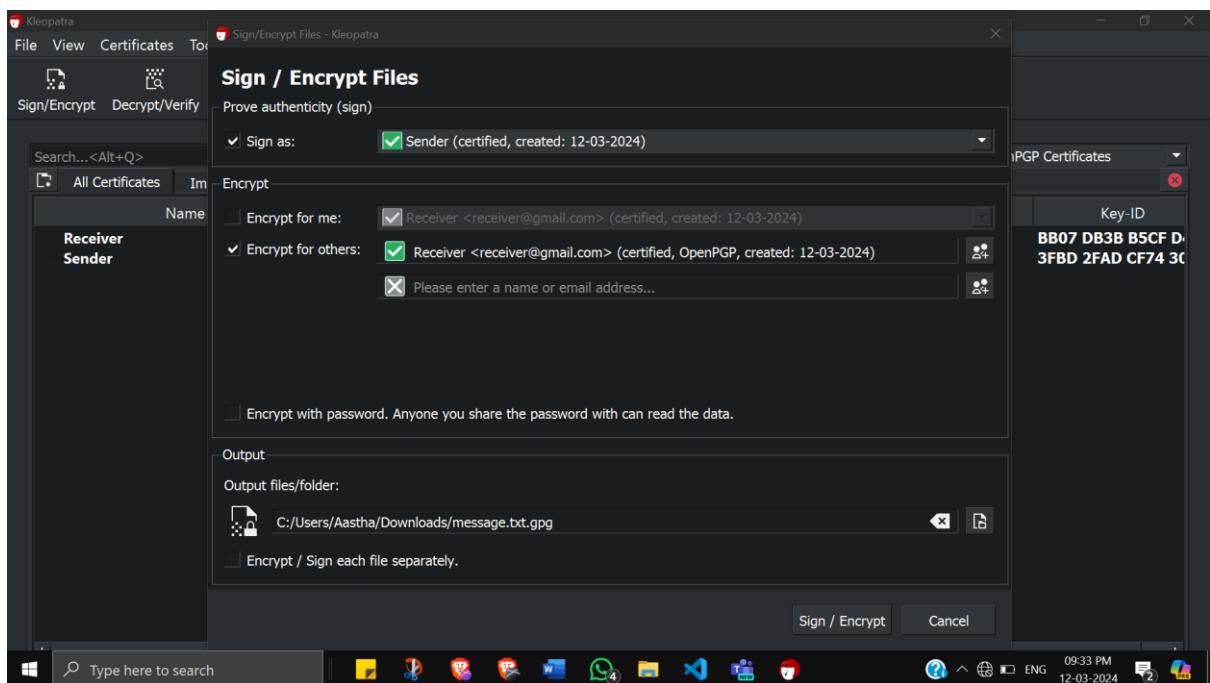

2. Go to File -> Sign/Encrypt. A pop up window will open from which you select message.txt.

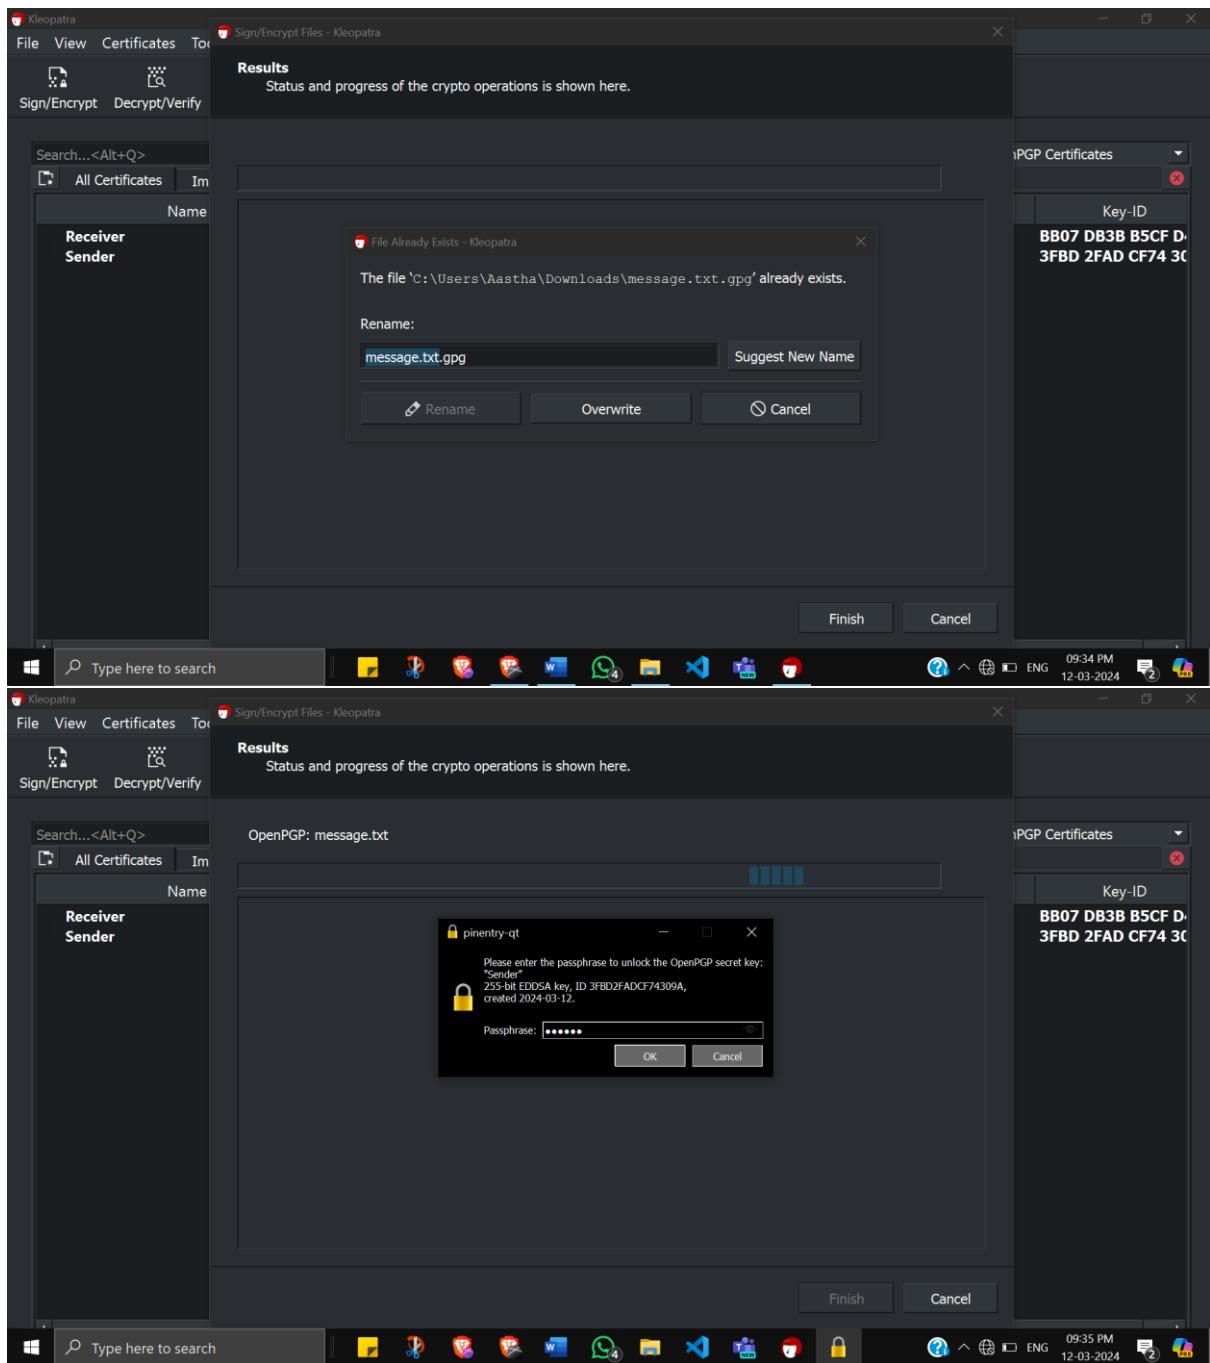

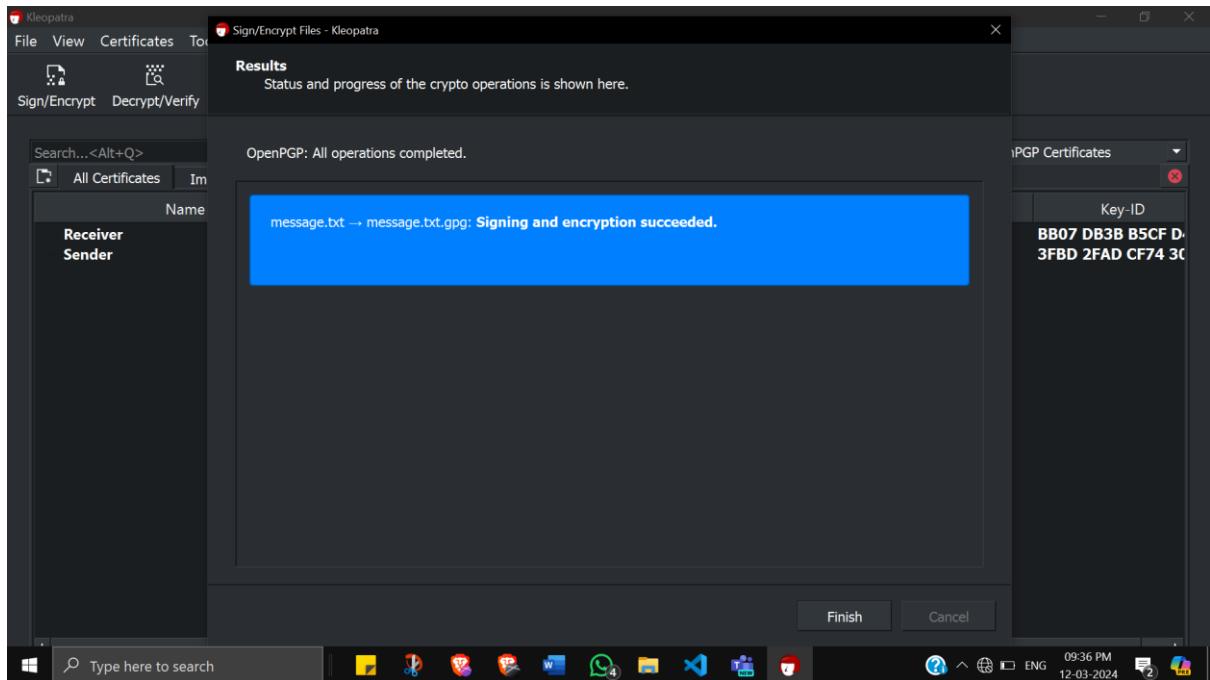

3. Select “Sender” beside “Sign as:” and “Receiver” beside “Encrypt for others:”. Click Sign/Encrypt.

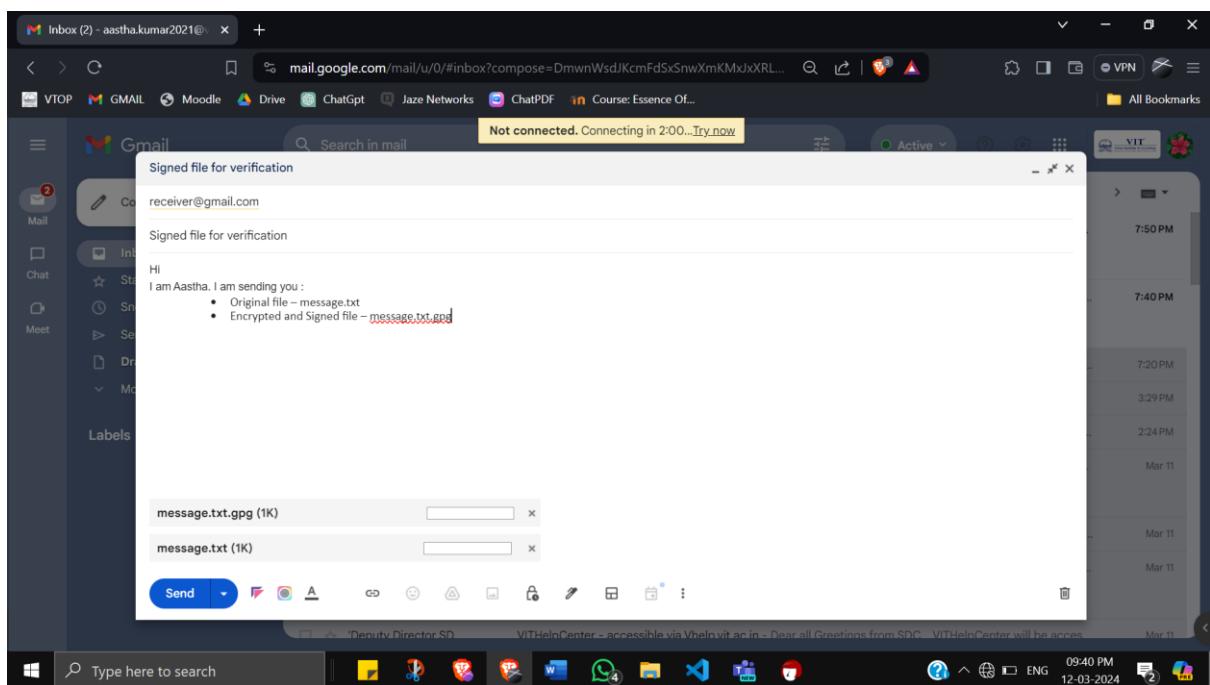

4. The new file will be encrypted, signed and saves as message.txt.gpg. Enter the Passphrase and click on “Finish”.

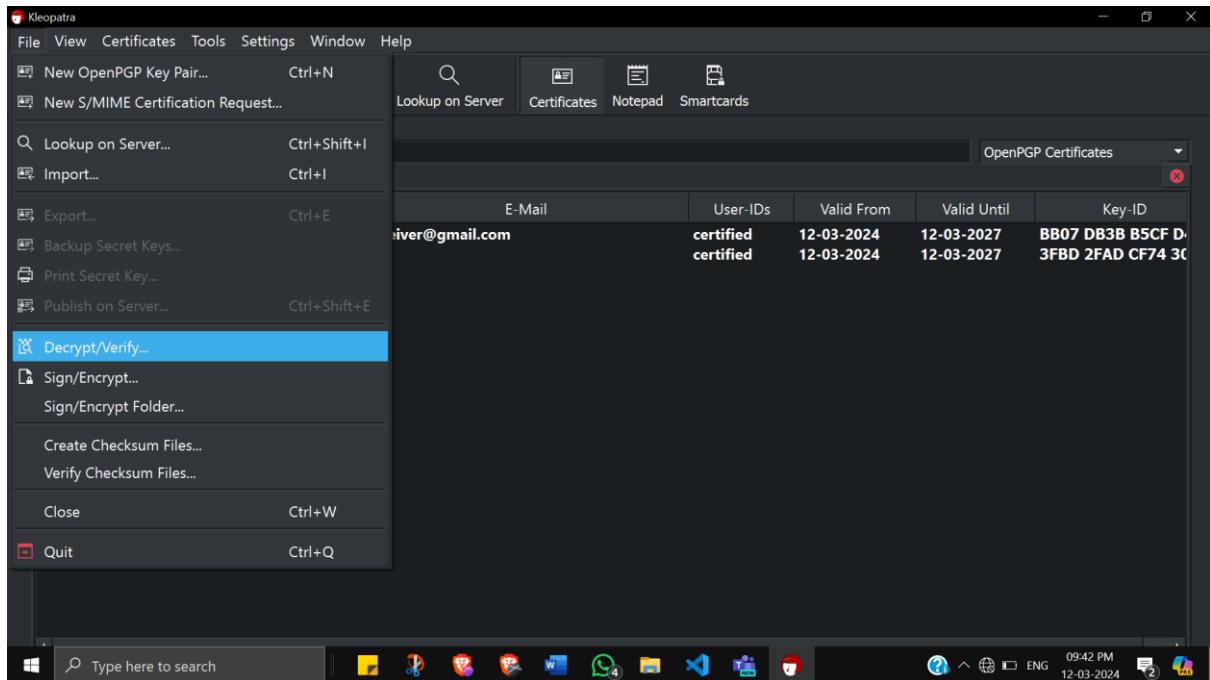

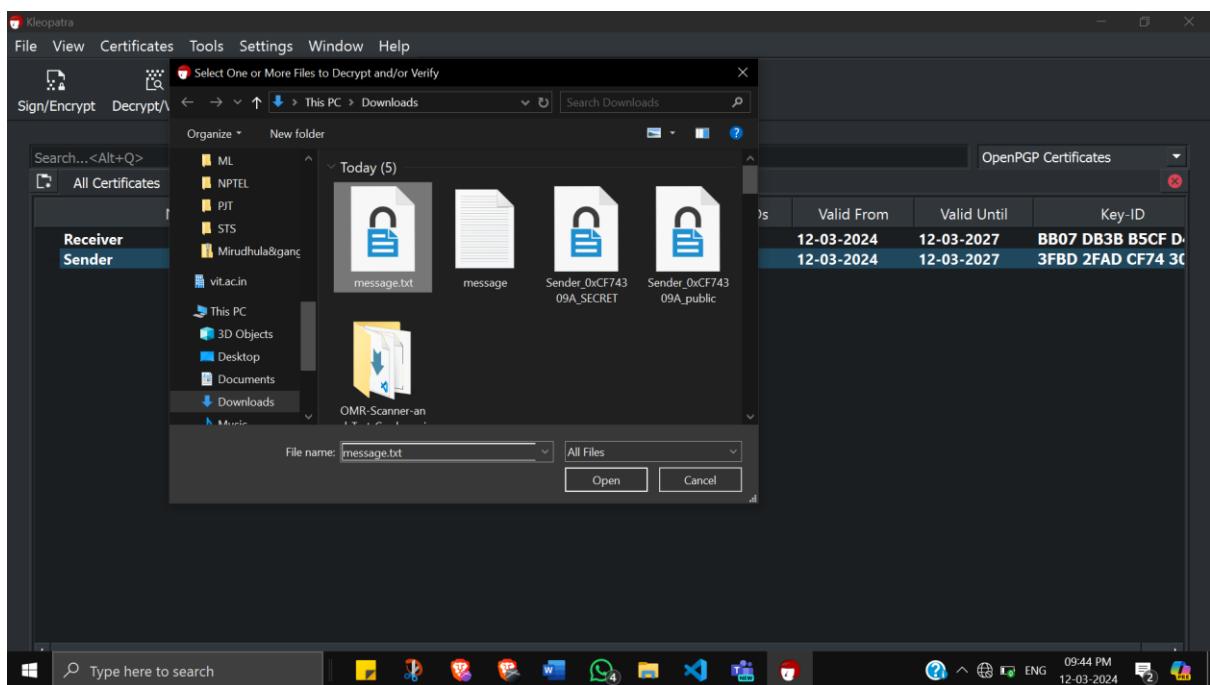

5. Now compose an email to the receiver and attach both files:-
 - Original file – message.txt
 - Encrypted and Signed file – message.txt.gpg

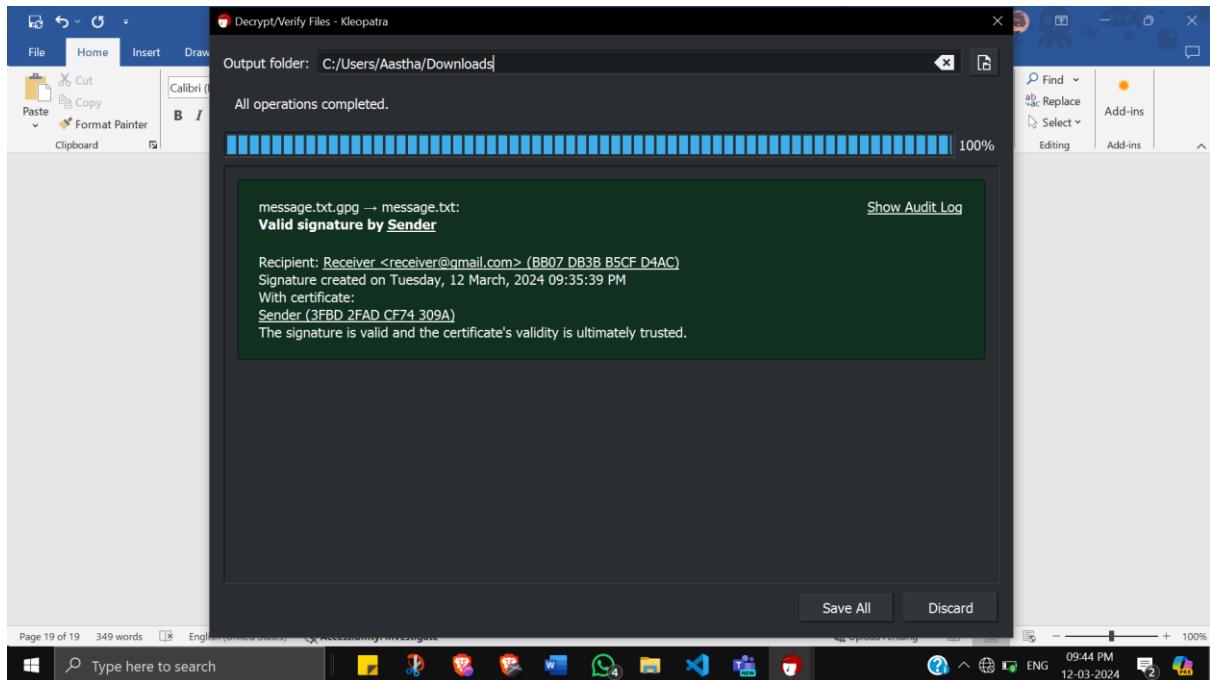

6. Now the recipient needs to verify the signature, for that they need to go to File -> Decrypt/Verify.

7. A pop up window will open from which you select message.txt.gpg. and click on “Open”

Observation:

- Encryption with Kleopatra: Encrypting a message using Kleopatra is straightforward. You can select the recipient's public key, enter the message, and encrypt it with just a few clicks. Kleopatra provides options for selecting encryption algorithms and adding additional security features such as digital signatures.
- Decryption with Kleopatra: Decrypting an encrypted message received from a sender is also simple using Kleopatra. You can import your private key and decrypt the message with ease. Kleopatra ensures secure decryption by verifying the authenticity of the sender's digital signature.
- Digital Signatures: Adding digital signatures to messages provides assurance of the sender's identity and the integrity of the message content. Verifying digital signatures using Kleopatra ensures that the message has not been tampered with during transmission.

Results:

1. Encryption and Decryption:

The encrypted message sent using Kleopatra was successfully decrypted by the recipient using their private key. This demonstrates the effectiveness of encryption in protecting the confidentiality of communication.

2. Digital Signatures:

The message signed with a digital signature using Kleopatra was successfully verified by the recipient using the sender's public key. The verification process ensures that the message originated from the claimed sender and has not been altered in transit.

EXPERIMENT 7

Aim:

Demonstrate the implementation of network intrusion detection using Snort

Experiment Objective:

1. Simulate a network attack from one machine to another within a controlled environment.
2. Configure Snort on the target machine to detect specific network activities.
3. Create a custom Snort rule to trigger an alert when outbound TCP traffic to a specific domain is detected.
4. Verify the effectiveness of the custom Snort rule by browsing to a designated website from the machine where Snort is running and observing the alert generated by Snort.

Introduction :

Network intrusion detection systems (NIDS) are crucial components of network security infrastructure, responsible for identifying and mitigating potential threats within a network. Snort is a widely used open-source NIDS capable of real-time traffic analysis and packet logging. In this experiment, we aim to demonstrate the practical application of Snort in detecting suspicious network activity.

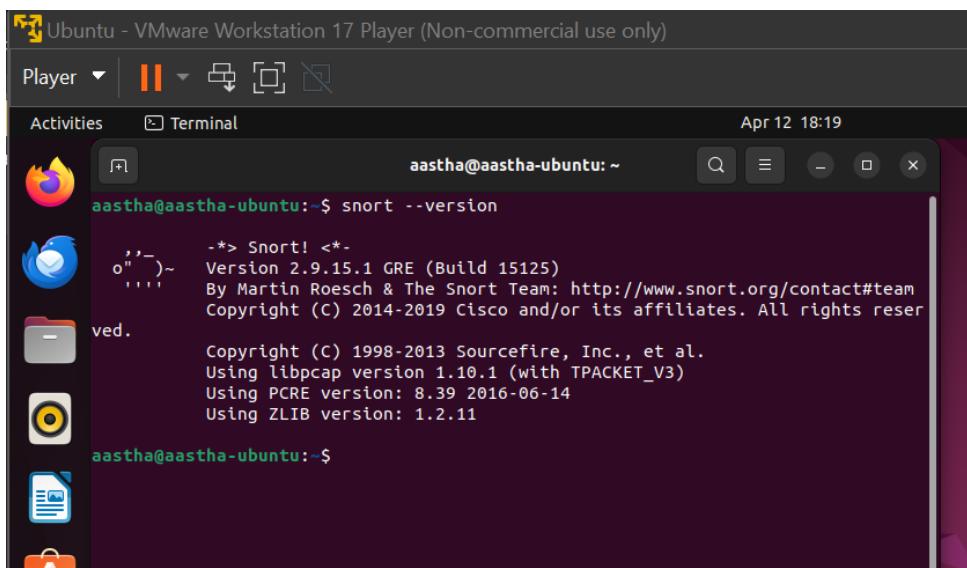

Setup:

- Operating Systems: Ubuntu and Kali Linux
- Snort: Install Snort on both the Ubuntu and Kali Linux machines. Snort can be installed using package managers or compiled from source. Ensure Snort is properly configured to monitor network traffic.
- Target Machine: Set up a target machine to simulate the attack. This machine will be the subject of the simulated attack and will run the services or applications to be exploited.
- Network Configuration: Ensure that the Ubuntu machine running Snort and the target machine are connected to the same network. This allows Snort to monitor network traffic between the two machines effectively.
- Custom Snort Rule: Create a custom Snort rule to detect outbound TCP traffic to the designated domain (craigslist.org). This rule should generate an alert when such traffic is detected.
- Testing: Perform testing by browsing to vit.ac.in from the machine where Snort is running. Monitor Snort alerts to verify that the custom rule correctly detects outbound TCP traffic to craigslist.org.

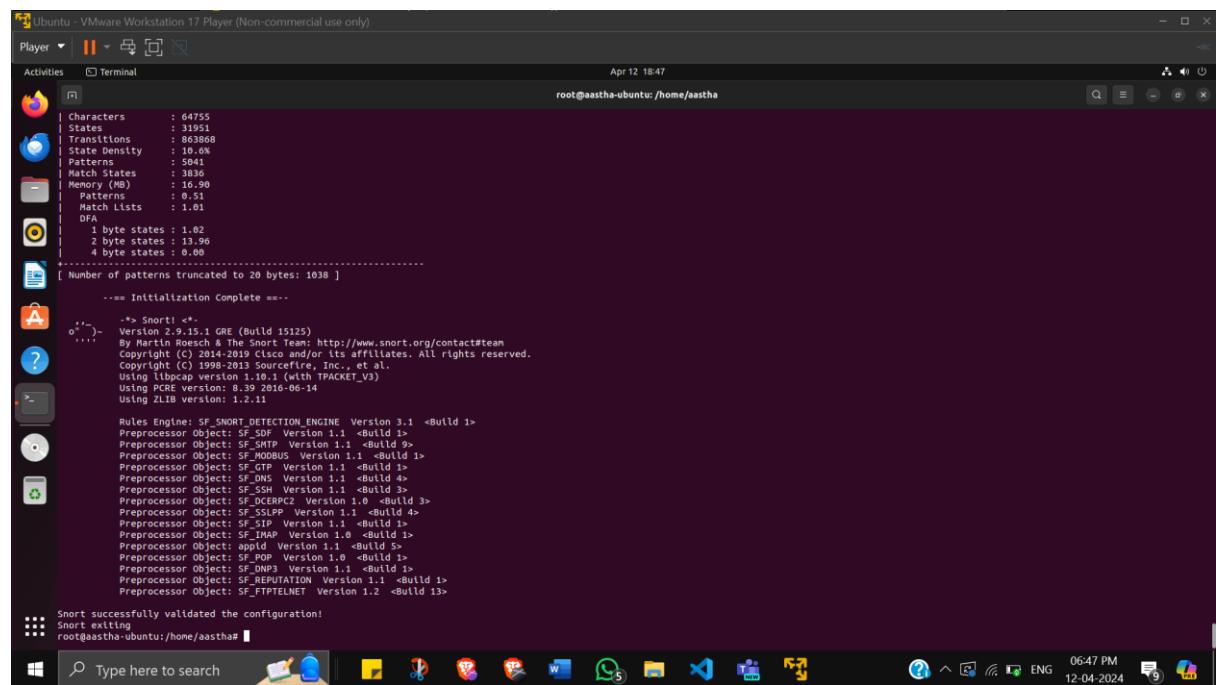

Experiment Steps:

Task 1: simulate attack on another machine.

1. Ensure Snort is already downloaded and configured on the Ubuntu machine. It can be checked by typing **snort –version**

2. Switch the root mode by typing in **sudo su** followed by your password. Then type in the following command to test if snort has properly been configured **sudo snort -T -c /etc/snort/snort.conf**

3. To start attack using Snort, type the following **sudo snort -A console -c /etc/snort/snort.conf**

```

aastha@aastha-ubuntu:~\$

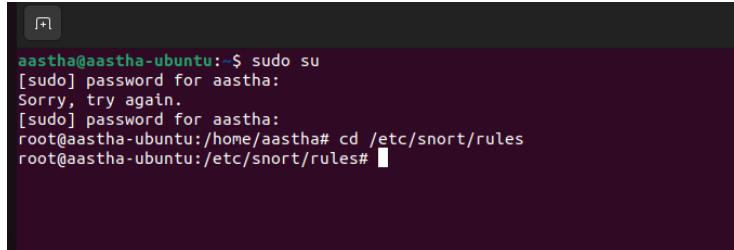

- Now the Kali machine will try to gain information on open ports on our Ubuntu machine using **nmap <ip address of Ubuntu>** i.e **nmap 192.168.163.130**

Commencing packet processing (pid=9109)
04/12/19:08:38.626073 [**] [1:14:21:11] SNMP AgentX/tcp request [**] [Classification: Attempted Information Leak] [Priority: 2] [TCP] 192.168.163.128:56134 -> 192.168.163.130:785
04/12/19:08:38.635064 [**] [1:14:18:11] SNMP request Tcp [**] [Classification: Attempted Information Leak] [Priority: 2] [TCP] 192.168.163.128:41774 -> 192.168.163.130:161

Snort picks up “attempted information leak” packets from Kali machine.

Task 2: create a rule in snort such that when you browse to vit.ac.in from the machine snort is running on, it should look for any outbound tcp request to craigslist.org and alert on it.

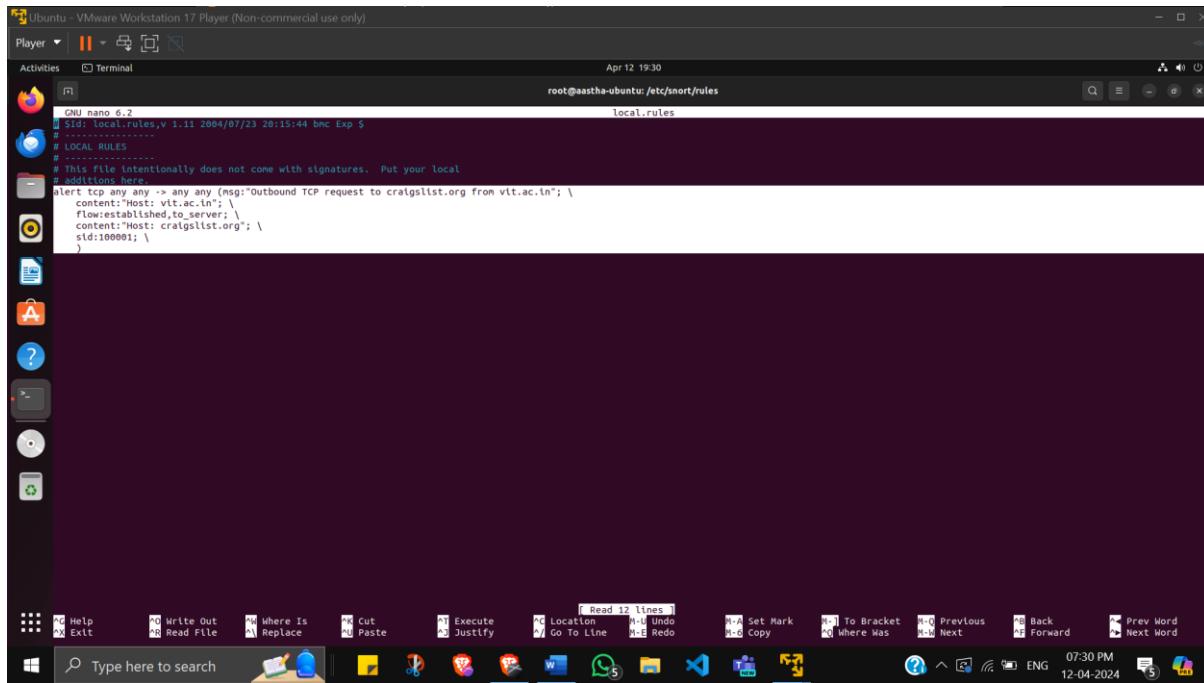

1. You need to create a rule to perform the above operation and then add it to the local rules directory under Snort rules. For this you need to navigate to the Snort Rules directory first by typing **cd /etc/snort/rules**

```
aastha@aastha-ubuntu:~$ sudo su
[sudo] password for aastha:
Sorry, try again.
[sudo] password for aastha:
root@aastha-ubuntu:/home/aastha# cd /etc/snort/rules
root@aastha-ubuntu:/etc/snort/rules#
```

Then open the local rules file in edit mode by typing **nano local.rules**. Type in the following rule:

```
alert tcp any any -> any any (msg:"Outbound TCP request to craigslist.org from vit.ac.in";
\content:"Host: vit.ac.in"; \flow:established,to_server; \content:"Host: craigslist.org";
\sid:100001; \)
```

2. Save the updated local.rules file by hitting **ctrl+X**, then **Y**, then **Enter**. The rule gets created.

Observations:

1. Simulated Attack: The simulated attack on the target machine was successful, as evidenced by the generated network traffic.
2. Snort Alerts: Snort successfully detected the outbound TCP traffic to craigslist.org, triggered by the custom rule created for this purpose.
3. Real-time Monitoring: Snort provided real-time monitoring of network traffic, allowing for immediate detection and response to suspicious activities.
4. Rule Configuration: The custom Snort rule effectively identified the specific network activity targeted in the experiment, demonstrating the flexibility and customization capabilities of Snort.

Results:

1. Detection of Outbound Traffic: Snort generated alerts for the outbound TCP traffic to craigslist.org as per the custom rule configuration.
2. Alerts Generated: The Snort alerts provided detailed information about the detected activity, including the source IP address, destination IP address, timestamp, and rule triggered.
3. Response to Threats: The ability of Snort to detect and alert on suspicious network activities enables network administrators to respond promptly to potential threats, enhancing overall network security.
4. Effectiveness of Custom Rule: The custom Snort rule accurately identified the specified outbound TCP traffic pattern, demonstrating its effectiveness in detecting specific network behaviors.
5. Validation of Security Measures: The successful detection of the simulated attack and the generation of alerts validate the effectiveness of Snort as a network intrusion detection system and highlight the importance of implementing robust security measures to safeguard network assets.
